To: <rruedy@giss.nasa.gov>

Dear Dr. Reto Ruedy,

I am a journalist from ÉPOCA, a Brazilian weekly magazine, and I am getting in contact to you following Mrs. Leslie McCarthy indication.

I am working on an article about the data correction made by Nasa at U.S. temperature tables and I would like to clarify some few points about this issue.

- What is the meaning of this correction? It is being said that it could raise questions about the trustability of the studies released about global warming. What is Nasa's official position towards it?
- Does Nasa intend to go public to explain more about the data correction?
- Is the global warming theory in risk because of this correction?
- Do you believe that this correction could be used for political purposes?

Dr. Reto, I am sending the questions to you via e-mail because I think it would be easier for you to answer (considering that my deadline is today) but I can call you if you prefer.

Thank you very much,

I look forward to hearing from you soon,

Best regards,

Letícia

Dear Dr. Reto,

I have just read your e-mail and I think that it is really clear about the implications (or lack of them) of this correction.

But I would like to ask you just two specific points, that I think that are still interesting even with your explanation:

- 1) Do the Nasa intend to go public to clarify this case and provide media and society with an official statement?
- 2) Other question raised by this case is about the differences among American temperature stations and the used in other countries. It's being said that American stations are mostly at rural areas, which suffered less temperature variation than the cities. Is it correct?

Thank you very much, once more,

Best regards,

Leticia

Subject: U.S. warmest years

From: Leticia Francisco Sorg - Redação Época - Editora Globo <lsorg@edglobo.com.br>

Date: Wed, 15 Aug 2007 14:03:26 -0300

To: <rruedy@giss.nasa.gov>

Dear Dr. Ruedy,

I would like to thank you very much for your attention and precise information.

The last point I would like to ask you is concerning the ranking of the warmest years in U.S.

I have organized the data from the previous and the correct table of temperatures and I got to this ranking:

Previous table

1°	1934
1°	1998
2°	1921
3°	1931
4°	2005
5°	1999
6°	2001
7°	1953
8°	1990
9°	1987

Revised table

1°	1934
2°	1998
3°	1921
4°	2006
5°	1931
6°	1999
7°	1953
8°	1990
9°	1938
10°	1939

As I've pointed in red, two years from 30's entered in the ranking of 10 warmest years in U.S.. Considering this change, would it be possible to say that the planet is becoming hotter and hotter?

Thank you once more,
Best regards,
Leticia

I have just read your e-mail and I think that it is really clear about the implications (or lack of them) of this correction.

But I would like to ask you just two specific points, that I think that are still interesting even with your explanation:

1) Do the Nasa intend to go public to clarify this case and provide media and society with an official statement?

Yes - what NASA would like to do is to use the media attention as an opportunity to educate the public about a truly serious situation. Exactly how they will do so - given the tiny size of the molehill that was blown up to enormous proportions - I don't know.

When in our January US table 1998 and 1934 changed places (in all our previous tables and publications US-1934 slightly beat US-1998) nobody noticed or cared about that change, much less made any kind of official statement. So why should we have to do it now ?

Small programming errors are made and corrected all the time; the one I made in 2000 was not the only one (like all other programmers, I make many mistakes every day - debugging usually finds them, but errors that have only small effects can survive for years).

2) Other question raised by this case is about the differences among American temperature stations and the used in other countries. It's being said that American stations are mostly at rural areas, which suffered less temperature variation than the cities. Is it correct?

One criticism that some people brought up was that weather stations near growing cities show rising temperature since the urbanization contributes a warming that would not be felt further away from the urban center.

This question was taken seriously, analyzed, it's effect compared to the margin of error and found to be of similar size to the margin of error. Nevertheless, we use an adjustment that makes the time series of urban stations behave exactly like the mean of the neighboring rural stations. If an urban station does not have neighboring rural stations, we do not use its data.

In spite of all this effort, the global warming deniers cling steadfastly to that effect.

Our analysis treats all stations the same way independent in which country they are located.

Subject: RES: U.S. warmest years

From: Leticia Francisco Sorg - Redação Época - Editora Globo <lsorg@edglobo.com.br>

Date: Wed, 15 Aug 2007 15:15:53 -0300

To: <rruedy@giss.nasa.gov>

Dear Dr. Ruedy,

Thank you very much for your explanation. But could we say that the temperature increasing rate is getting bigger in the last decades? It's being publicized that the the global temperatures are increasing at a rate of 0,2°C per decade in the last to decades, compared to a rate of less than 0,1 °C per decade in the beginning of the 20th Century.

Is this correct?

Thank you,

Sincerely

Assunto: Re: U.S. warmest years

Dear Leticia,

I agree with your revised table; I don't know where your previous table comes from (I'll look into that).

To answer your question, given the existing sampling error (.1-.2C):

Nò - we cannot draw any conclusions about our planet from the US data (much less from the rankings you show below):

The US has been warming in the period 1980-2006 similarly to the period from 1920-1934; that earlier 15-year period then was followed by a cooling period and the same might be true for the current 25-year period. The annual US-mean changes are still large compared to any CO2 effect.

However, the global means show a totally different picture (global mean year-to-year changes being much smaller than US-mean year-to-year changes); and whereas no scientist, as far as I know, could make a convincing argument for an extended warming period in the US in 1920-1934, our 1982 model runs showed that the effect of CO2 should become noticeable in the global means within the next 2-4 decades. And sadly, the global (not the US) data now available showed that model was, if anything, underestimating the effect.

Sincerely,

Reto

Assunto: Re: RES: U.S. warmest years

Dear Leticia,

This is even more speculative, some people still try to deny in spite of the data that it is warming at all. To observe that the warming accelerates would take even longer observation times, another 50-100 years.

It would be bad enough if it keeps increasing at the current rate of .2C/decade as it has since 1980. It briefly increased at almost that rate in the 1915-1945 period but then it stayed even or even decreased a little til about 1980. The period from 1880-1920 was a period of basically constant global temperatures.

Again, the frightening thing about today's temperature rise is that it was predicted 25 years ago based on solid physics. So chances are it will not stop until we deal with the cause of it ! The good thing is that we know the cause, and we could use that knowledge if people just paid attention to the experts rather than to the bloggers.

10°

1939

As I've pointed in red, two years from 30's entered in the ranking of 10 warmest years in U.S.. Considering this change, would it be possible to say that the planet is becoming hotter and hotter?

Thank you once more,
Best regards,
Letícia

Again, the frightening thing about today's temperature rise is that it was predicted 25 years ago based on solid physics. So chances are it will not stop until we deal with the cause of it ! The good thing is that we know the cause, and we could use that knowledge if people just paid attention to the experts rather than to the bloggers.

Dear Dr. Ruedy,

Thank you very much for your explanation. But could we say that the temperature increasing rate is getting bigger in the last decades? It's being publicized that the the global temperatures are increasing at a rate of 0,2°C per decade in the last to decades, compared to a rate of less than 0,1 °C per decade in the beginning of the 20th Century.

Is this correct?

Thank you,
Sincerely

Assunto: Re: U.S. warmest years

Dear Leticia,

I agree with your revised table; I don't know where your previous table comes from (I'll look into that).

To answer your question, given the existing sampling error (.1-.2C):

No - we cannot draw any conclusions about our planet from the US data (much less from the rankings you show below):

The US has been warming in the period 1980-2006 similarly to the period from 1920-1934; that earlier 15-year period then was followed by a cooling period and the same might be true for the current 25-year period. The annual US-mean changes are still large compared to any CO2 effect.

However, the global means show a totally different picture (global mean year-to-year changes being much smaller than US-mean year-to-year changes); and whereas no scientist, as far as I know, could make a convincing argument for an extended warming period in the US in 1920-1934, our 1982 model runs showed that the effect of CO2 should become noticeable in the global means within the next 2-4 decades. And sadly, the global (not the US) data now available showed that model was, if anything, underestimating the effect.

Sincerely,

Reto

Dear Dr. Ruedy,

I would like to thank you very much for your attention and precise information.

The last point I would like to ask you is concerning the ranking of the warmest years in U.S.

I have organized the data from the previous and the correct table of temperatures and I got to this ranking:

Previous table

1°
1934
1°
1998
2°
1921
3°
1931
4°
2005
5°
1999
6°
2001
7°
1953
8°
1990
9°
1987

Revised table

1°
1934
2°
1998
3°
1921
4°
2006
5°
1931
6°
1999
7°
1953
8°
1990
9°
1938
10°
1939

As I've pointed in red, two years from 30's entered in the ranking of 10 warmest years in U.S.. Considering this change, would it be possible to say that the planet is becoming hotter and hotter?

Thank you once more,
Best regards,
Leticia

Jim, I'm afraid your note doesn't clarify things. This part makes no sense:

"Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record." The year 1934 isn't on NASA's previous list of the five warmest years, as Volz notes. It does, indeed, look as if "suddenly 1934 has become the warmest U.S. year."

Also: Critics say you've refused to share the algorithm used to generate your graph data. Why haven't you? And might the flaw have been spotted sooner if the public had been able to inspect it?

Feel free to call if that's easier.

Best,
Demian

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Re: Fwd: FW: <no subject>

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intent of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Columnist Notes Changes In NASA's Temperature Data. **In an op-ed for the Washington Times (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other

day. If you go to NASA's Web site and look at the " U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century - 2000, 2002, 2003, 2004 - plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings - albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

*

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website

http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the *Washington Times* (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even American: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Thanks, James. I'm not familiar with that paper from 2001. Is it not true, though, that NASA's rankings, as available at:

<http://data.giss.nasa.gov/gistemp/graphs/Fig.D.txt>

now show 1934 as the hottest year, where 1998 used to hold that position?

thanks,
demian

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper,

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper,

at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged sweeterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even American: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper,

1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intent of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the *Washington Times* (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hallinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look

at the " U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Thanks for the quick reply, Reto.

----- Original Message -----

From: Reto Ruedy <rruedy@giss.nasa.gov>

At: 8/14 13:58:38

Jim,

The US plots and figures are not part of the standard analysis; once a year (in January) we create them in a separate step.

In the last posting visible to the public (done in Jan 2001) of the US annual temperature plot 1998 was indeed a little warmer than 1934. In order to notice that, you had to go to the plot and click on table data. As far as I know, nobody at GISS noticed that fact or gave it a second thought.

The next update was due in Jan 2008. Had we updated this figure every month, then due to late US station reports, at some point that ranking would have changed back to 1934 "beating" 1998. My guess is that it would have been in February for the following reason:

Ken downloads the GHCN data repeatedly until he sees some US stations included - they always seem to come in a day or 2 later than most other data. As you know, particularly in January there is pressure to do the update as soon as possible; so it is very likely that his final download in January did not include all US stations yet.

I of course wanted to see the impact of the correction only, hence I did the same analysis for the latest data with and without the correction. In both cases, as you reported, US-1934 was slightly warmer than US-1998.

Hope that clears it all up.

Reto

On Tue, 2007-08-14 at 13:27 -0400, James Hansen wrote:

Makiko, Reto, could you please clear this up. Other people keep saying the same thing that Demian does, i.e., that we previously claimed that 1998 was warmer than 1934. Is that right? I am quite sure that our 2001 paper shows 1934 slightly warmer, as we still find. Of course, scientifically this is all nonsense, as the difference of 0.02 is much less than the accuracy, so practically it should be stated as a tie. I know that whenever new stations are added to the record it can change things by small amounts. Did we once find 1998 as warmer??? Jim (I will be away from e-mail for a few hours).

On 8/14/07, DEMIAN MCLEAN, BLOOMBERG/ NEWSROOM:
<dmclean8@bloomberg.net> wrote:

Thanks, James. I'm not familiar with that paper from 2001. Is it not true, though, that NASA's rankings, as available at:

<http://data.giss.nasa.gov/gistemp/graphs/Fig.D.txt>

now show 1934 as the hottest year, where 1998 used to hold

that position?

thanks,
demian

----- Original Message -----

At: 8/14 13:00:38

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month.

The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intent of these critics/contrarians, one should

note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the Washington Times (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the " U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century - 2000, 2002, 2003, 2004 - plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of

America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

American climate data so much better he's not

The Real Deal: Usufruct & the Gorilla

Fox, Washington Times, and their like have gone bananas over a flaw discovered in the computer program that produces global temperatures at GISS each month. They have even managed to get Congress and NASA Headquarters involved. Now we know what mom meant when she said "don't make a federal case out of it". Hey, what is really going on here?

The said computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001) http://pubs.giss.nasa.gov/docs/2001/2001_Hansen_etal.pdf The flaw affected temperatures only in the United States (by about 0.15°C) and only in 2000 and later. We corrected the flaw in the program, thanked the fellow who pointed it out, and thought that was the end of it.

[The correction: As explained in the e-mail sent last week, http://www.columbia.edu/~leh1/distro_LightUpstairs_70810.pdf one improvement made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the U.S. as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day of temperature measurements, etc. Our computer program presumed that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program instead picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

What we have here is a case of dogged contrarians who present results in ways intended to deceive the public into believing that the changes have greater significance than reality. They aim to make a mountain out of a mole hill. I believe that these people are not stupid, instead they

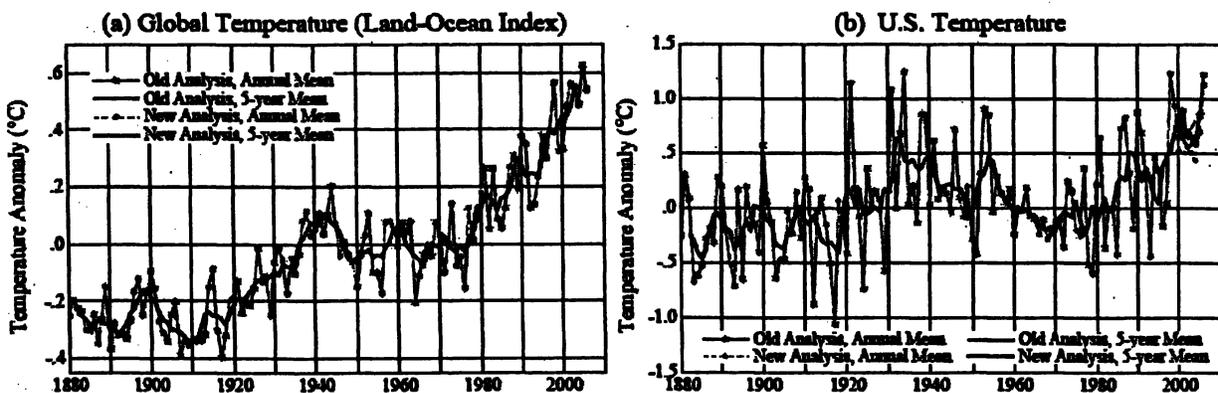

Figure 1. Global (a) and U.S. (b) before and after correction of flaw in computer program.

seek to create a brouhaha and muddy the waters in the climate change story. They seem to know exactly what they are doing and believe they can get away with it, because the public does not have the time, inclination, and training to discern what is a significant change with regard to the global warming issue.

The proclamations of the contrarians are a deceit, but their story raises a more important matter, usufruct. It is the most important issue in the entire global warming story, in my opinion. The players in the present U.S. temperature story, we scientists included, are just bit players. The characters in the main drama are big fish, really big fish. But before we get to that matter, I need to expose how the deceit works.

Instead of showing the impact of the flaw in our analysis program via a graph such as Figure 1, as a scientist would do (and as would immediately reveal how significant the flaw was), they instead discuss ranking of temperature in different years, including many false statements. We have thus been besieged by journalists saying "they say that correcting your error caused the warmest year to become 1934 rather than a recent year, is that right!?"

Hardly. First of all, many journalists had the impression that they were talking about global temperature. As you can see from Figure 1a, global warming is unaffected by the flaw. This realization should be enough to make most journalists lose interest, as global warming refers to global temperature.

But what if you are a chauvinist and only care about temperature in the United States? Did correcting the flaw in the program change the time of calculated maximum temperature to 1934? No. If you look at our 2001 paper, and get out your micrometer, you will see that we found 1934 to be the warmest year in the United States, by a hair, of the order of 0.01°C warmer than 1998, the same as the result that we find now. Of course the difference in the 1934 and 1998 temperatures is not significant, and we made clear in our paper that such years have to be declared as being practically a dead-heat.

Indeed, when we receive new data each month, which often adds in new stations, or modifies the results at a small number of stations, the results for a given year can fluctuate as much as a few hundredths of a degree. Also the GISS ranking of years is commonly different than that obtained from the NOAA or British analyses. This is expected, as there are significant differences in the methods. For example, the urban warming that we estimate (and remove) is larger than that used by the other groups (as discussed in 2001 Hansen et al. reference above).

Let's look (Figure 2) at the temperature anomalies in the four years that yield the warmest U.S. in our analysis. The U.S. mean temperature anomalies that we obtain range from 1.25°C in 1934 to 1.13°C in 2006. Thus the total range among these four years is just over a tenth of a degree. The uncertainty in the U.S. temperature is at least that large (see our published papers), so we can only say that these four years were comparably warm and the warmest year was probably either 1934 or 1998.

Note, however, that the 1998 and 2006 temperature anomaly maps differ fundamentally from the 1934 and 1921 temperature maps. In 1998 and 2006 the world as a whole has become warmer, 1998 being aided by a very strong El Nino, but 2006 by only a very weak El Nino. In 1921 and 1934 the United States happened to be relatively hot spot compared to the world as a whole. The next time that the U.S. temperature happens to be unusually high relative to the globe, it may be quite a barn burner.

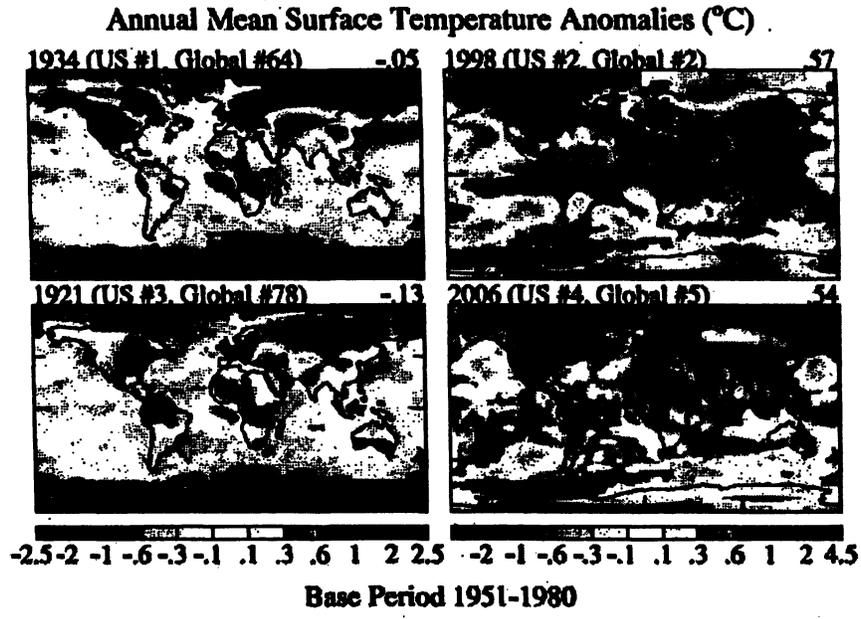

Figure 2. Temperature anomalies, relative to 1951-1980 base period, in the four years that are the warmest in the contiguous U.S. in the GISS analysis.

Although the media is always very interested in the ranking of individual years, the precise ranking is not only difficult to define accurately, it is also less important than the climate change averaged over several years. Figure 3 shows surface temperature anomalies of the past 10 years relative to both a 1880-1920 base period and the usual 1951-1980 base period. The figure also shows these results both with and without the flaw in our temperature analysis.

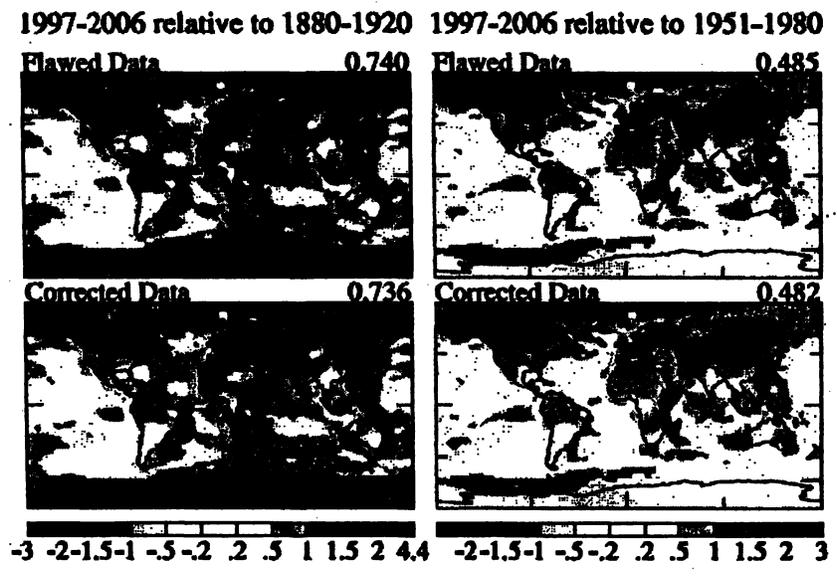

Figure 3. Surface temperature anomalies in the past 10 years (1997-2006) relative to two alternative base periods, 1880-1920 on the left and 1951-1980 on the right. The top row versus the bottom row shows the effect of the data flaw.

Over the past 30 years temperature isotherms have been moving poleward in the Northern Hemisphere land areas at a rate of about 50 km per decade. If the movements were fluctuations, their impacts would be limited. However, continual change of the same sense has a cumulative effect on the ability of species to survive in the presence of other stresses. Moreover, under business-as-usual growth of greenhouse gas emissions the rate of movement of isotherms could double this century, as discussed in several papers available on our web site, including "Dangerous" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_1.pdf "Trace Gases" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_2.pdf

Implications of this rapid and growing global climate change are discussed in "The 800 Pound Gorilla: The Threat and Taming of Global Climate Change",

"Gorilla" [Need hyperlink here](#)

"Gorilla" is adapted from "The Threat to the Planet" (13 July 2006 New York Rev. Books) with assistance of Walter Simpson. "Gorilla" includes sidebars on 'Likely Consequences of Global Climate Change' and 'Three Policies Needed to Defuse the Global Warming Time Bomb'.

Usufruct. The deceit behind the attempts to discredit evidence of climate change reveals matters of importance. This deceit has a clear purpose: to confuse the public about the status of knowledge of global climate change, thus delaying effective action to mitigate climate change. The danger is that delay will cause tipping points to be passed, such that large climate impacts become inevitable, including the loss of all Arctic sea ice, destabilization of the West Antarctic ice sheet with disastrous sea level rise later this century, and extermination of a large fraction of animal and plant species (see "Dangerous", "Trace Gases", and "Gorilla" papers).

Make no doubt, however, if tipping points are passed, if we, in effect, destroy creation, passing on to our children, grandchildren, and the unborn a situation out of their control, the contrarians who work to deny and confuse will not be the principal culprits. The contrarians will be remembered as court jesters. There is no point to joust with court jesters. They will always be present. They will continue to entertain even if the Titanic begins to take on water. Their role and consequence is only as a diversion from what is important.

The real deal is this: the royalty controlling the court, the ones with the power, the ones with the ability to make a difference, with the ability to change our course, the ones who will live in infamy if we pass the tipping points, are the captains of industry, CEOs of EXXON/Mobil and fossil fuel leaders, automobile manufacturers, utilities, all of the leaders who have placed short-term profit above the fate of the planet and the well-being of our children. The court jesters are their jesters, occasionally paid for services, and more substantively supported by the captains' disinformation campaigns.

Court jesters serve as a distraction, a distraction from usufruct. Usufruct is the matter that the captains wish to deny, the matter that they do not want their children to know about. They realize that if there is no 'gorilla', than usufruct is not an important issue for them. So, with the help of jesters, they deny the existence of the gorilla. There is no danger of melting the Arctic, of destabilizing the West Antarctic ice sheet, of increasing hydrologic extremes, more droughts and stronger forest fires on the one hand and heavier downpours and floods on the other, threats to the fresh water supplies of huge numbers of people in different parts of the globe. "Whew! It is lucky that, as our jesters show, these are just imaginary concerns. We captains of industry can continue with business-as-usual, we do not need to face the tough problem of how to maintain profits without destroying our legacy in our children's eyes."

Usufruct is as American as the Declaration of Independence, implicit in the Preamble "...to ourselves and our Posterity...". It is explicitly discussed in a famous letter of 6 September

1789 from Thomas Jefferson to James Madison, discussing the proposed Bill of Rights to be added to the Constitution: "The question whether one generation of men has a right to bind another. . . is a question of such consequences as not only to merit decision, but place also among the fundamental principles of every government. . . . I set out on this ground, which I suppose to be self-evident, 'that the earth belongs in usufruct to the living' . . ."

Jefferson's philosophy regarding generational relations was based on this "self-evident" principle. That we have an obligation to preserve creation for today's and future generations is a widely held belief. Native American Oren Lyons, a Faithkeeper in the Onondaga Nation, discusses the belief of Native Americans in their obligations to the "seventh generation". It is also a biblical paradigm that the Earth, Creation, is an intergenerational commons, the fruits and benefits of which should be accessible to every member of every generation.

Is the principle that the Earth belongs to us only in usufruct indeed self-evident and accepted by the public? In "Gorilla" I note the observation of Larry King that "nobody cares about 50 years from now". We can't take both positions. We need to make up our mind.

I am puzzled by views expressed by some conservatives, views usually expressed in vehement unpleasant ways in e-mails that I have been bombarded by in the past several days. It is a bit disconcerting as I come from a moderately conservative state, and I consider myself a moderate conservative in most ways. It is puzzling, because it seems to me that conservatives should be the first ones standing up for preserving Creation, and for the rights of the young and the unborn. That is the basic intergenerational issue in global warming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

Is it possible that conservatives have been too quick to support the captains of industry? If we allow industry to continue on a path of denial, to focus on their short-term profits, to deny the rights of our children, grandchildren and the unborn, if the planet passes climate tipping points, will we not share in the infamy, the infamy of the captains of industry?

It seems to me that the present situation, with only minimalist actions to mitigate global climate change, reflects, at least in part, the "success" of the disinformation campaign that the captains of industry have at least tolerated, and, in some cases, encouraged and supported. Of course nature is going to, eventually, reveal the truth, but there is potentially great harm in the disinformation, because it increases the likelihood that we will pass climate tipping points.

The captains of industry are smarter than their jesters. They cannot pretend that they are unaware of climate change dangers and consequences for future generations. It is time for the captains of industry to rethink their positions. I do not mean, time to polish their image with marginal investments, 'green' advertisements, and other public relations gimmicks. I mean, time to consider how they will function as we move toward a cleaner world 'beyond petroleum', to invest in approaches that will help take us from here to there, and to begin to move smartly in that direction. There is still time to avert the most dramatic climate effects, if we promptly begin to address both CO₂ and non-CO₂ climate forcings. But just barely.

I am indebted to Jim Wine for schooling me in 'usufruct'.

Criticisms, as always, are welcome.

I made two additional changes: adding "in 2001" after jump, and moving the paragraph just before Figure 2 to just after Figure 2. Note that I removed the line To be removed from Jim Hansen's e-mail list respond to sender with REMOVE as subject but this line should be included in the e-mail.

On 8/10/07, James Hansen <jhansen@giss.nasa.gov> wrote:

These changes are fine, but they need to be made to the attached version. We need to send it to the media list soon. Jim

Jim,

Please read this remark of Robert's and make the change unless you really want it to be ARE.

>When I view the Word DOC there is no degree sign in 0.15 deg-C.
>Is that intentional?

I think SI unit doesn't have degree symbol, so just 0.15C, but I think it is clearer to have the usual small circle high up or write down deg. Jim made it 0.15C, so maybe he is using the SI unit.

>The phrase "order one-thousands" should be "order one-thousandth".

Yes, you are right. I will make the change

The Real Deal: Usufruct & the Gorilla

Fox, Washington Times, and their like have gone bananas over a flaw discovered in the computer program that produces global temperatures at GISS each month. They have even managed to get Congress and NASA Headquarters involved. Now we know what mom meant when she said "don't make a federal case out of it". Hey, what is really going on here?

The said computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001) http://pubs.giss.nasa.gov/docs/2001/2001_Hansen_etal.pdf The flaw affected temperatures only in the United States (by about 0.15°C) and only in 2000 and later. We corrected the flaw in the program, thanked the fellow who pointed it out, and thought that was the end of it.

[The correction: As explained in the e-mail sent last week, http://www.columbia.edu/~leh1/distro_LightUpstairs_70810.pdf one improvement made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the U.S. as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day of temperature measurements, etc. Our computer program presumed that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program instead picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

What we have here is a case of dogged contrarians who present results in ways intended to deceive the public into believing that the changes have greater significance than reality. They aim to make a mountain out of a mole hill. I believe that these people are not stupid, instead they

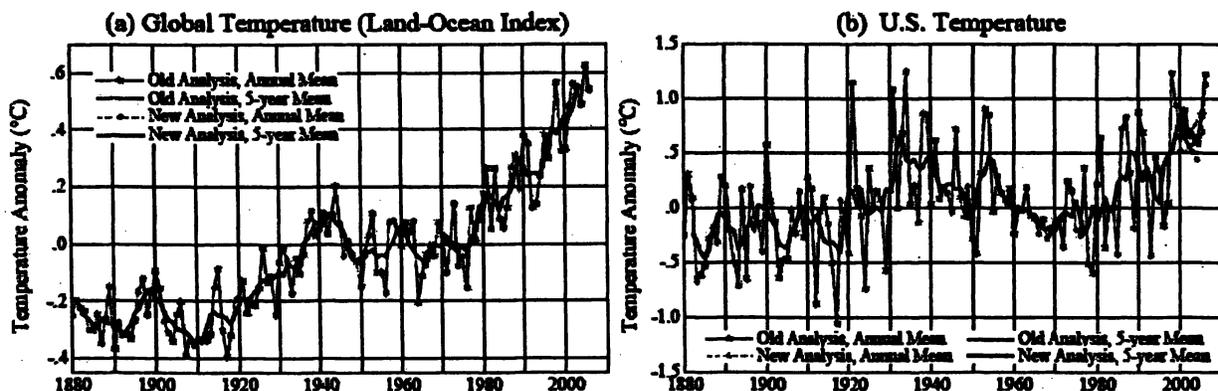

Figure 1. Global (a) and U.S. (b) before and after correction of flaw in computer program.

seek to create a brouhaha and muddy the waters in the climate change story. They seem to know exactly what they are doing and believe they can get away with it, because the public does not have the time, inclination, and training to discern what is a significant change with regard to the global warming issue.

The proclamations of the contrarians are a deceit, but their story raises a more important matter, usufruct. It is the most important issue in the entire global warming story, in my opinion. The players in the present U.S. temperature story, we scientists included, are just bit players. The characters in the main drama are big fish, really big fish. But before we get to that matter, I need to expose how the deceit works.

Instead of showing the impact of the flaw in our analysis program via a graph such as Figure 1, as a scientist would do (and as would immediately reveal how significant the flaw was), they instead discuss ranking of temperature in different years, including many false statements. We have thus been besieged by journalists saying "they say that correcting your error caused the warmest year to become 1934 rather than a recent year, is that right!?"

Hardly. First of all, many journalists had the impression that they were talking about global temperature. As you can see from Figure 1a, global warming is unaffected by the flaw. This realization should be enough to make most journalists lose interest, as global warming refers to global temperature.

But what if you are a chauvinist and only care about temperature in the United States? Did correcting the flaw in the program change the time of calculated maximum temperature to 1934? No. If you look at our 2001 paper, and get out your micrometer, you will see that we found 1934 to be the warmest year in the United States, by a hair, of the order of 0.01°C warmer than 1998, the same as the result that we find now. Of course the difference in the 1934 and 1998 temperatures is not significant, and we made clear in our paper that such years have to be declared as being practically a dead-heat.

Indeed, when we receive new data each month, which often adds in new stations, or modifies the results at a small number of stations, the results for a given year can fluctuate as much as a few hundredths of a degree. Also the GISS ranking of years is commonly different than that obtained from the NOAA or British analyses. This is expected, as there are significant differences in the methods. For example, the urban warming that we estimate (and remove) is larger than that used by the other groups (as discussed in 2001 Hansen et al. reference above).

Let's look (Figure 2) at the temperature anomalies in the four years that yield the warmest U.S. in our analysis. The U.S. mean temperature anomalies that we obtain range from 1.25°C in 1934 to 1.13°C in 2006. Thus the total range among these four years is just over a tenth of a degree. The uncertainty in the U.S. temperature is at least that large (see our published papers), so we can only say that these four years were comparably warm and the warmest year was probably either 1934 or 1998.

Note, however, that the 1998 and 2006 temperature anomaly maps differ fundamentally from the 1934 and 1921 temperature maps. In 1998 and 2006 the world as a whole has become warmer, 1998 being aided by a very strong El Nino, but 2006 by only a very weak El Nino. In 1921 and 1934 the United States happened to be relatively hot spot compared to the world as a whole. The next time that the U.S. temperature happens to be unusually high relative to the globe, it may be quite a barn burner.

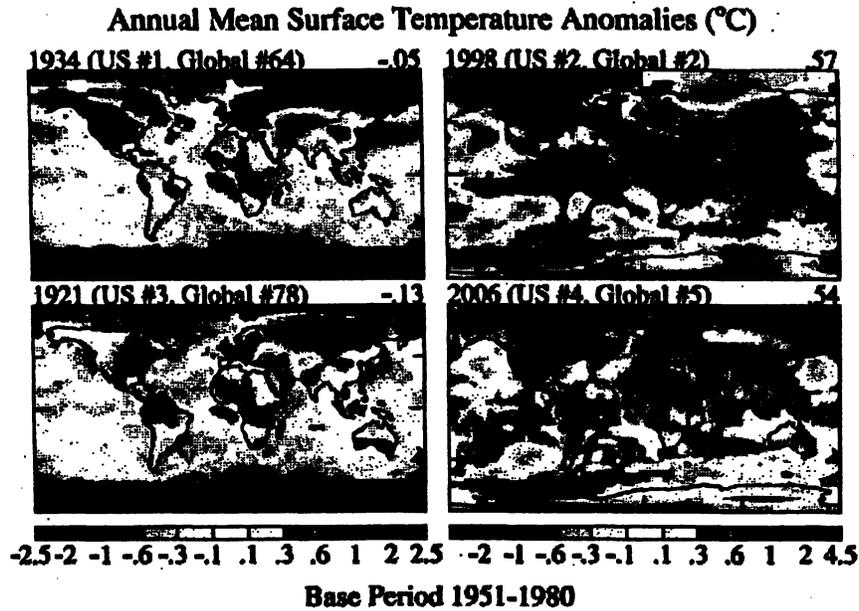

Figure 2. Temperature anomalies, relative to 1951-1980 base period, in the four years that are the warmest in the contiguous U.S. in the GISS analysis.

Although the media is always very interested in the ranking of individual years, the precise ranking is not only difficult to define accurately, it is also less important than the climate change averaged over several years. Figure 3 shows surface temperature anomalies of the past 10 years relative to both a 1880-1920 base period and the usual 1951-1980 base period. The figure also shows these results both with and without the flaw in our temperature analysis.

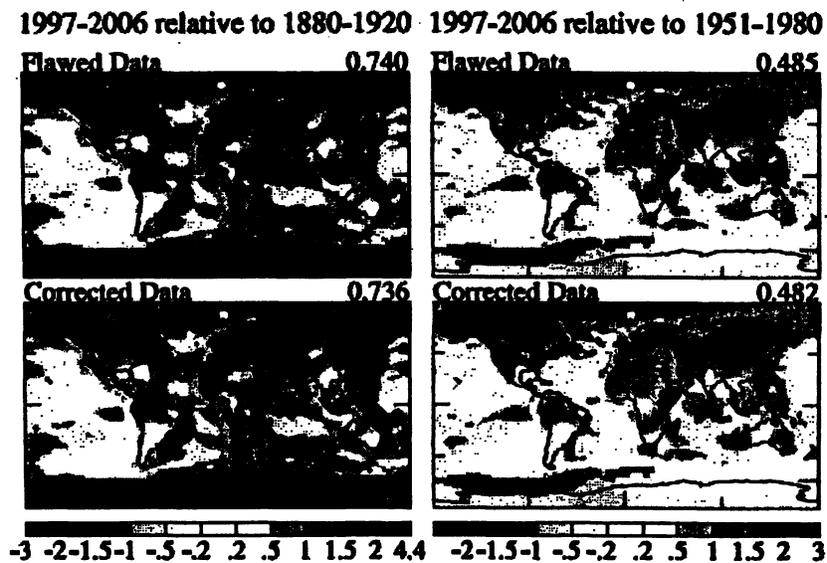

Figure 3. Surface temperature anomalies in the past 10 years (1997-2006) relative to two alternative base periods, 1880-1920 on the left and 1951-1980 on the right. The top row versus the bottom row shows the effect of the data flaw.

Over the past 30 years temperature isotherms have been moving poleward in the Northern Hemisphere land areas at a rate of about 50 km per decade. If the movements were fluctuations, their impacts would be limited. However, continual change of the same sense has a cumulative effect on the ability of species to survive in the presence of other stresses. Moreover, under business-as-usual growth of greenhouse gas emissions the rate of movement of isotherms could double this century, as discussed in several papers available on our web site, including "Dangerous" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_1.pdf "Trace Gases" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_2.pdf

Implications of this rapid and growing global climate change are discussed in "The 800 Pound Gorilla: The Threat and Taming of Global Climate Change",

"Gorilla" [Need hyperlink here](#)

"Gorilla" is adapted from "The Threat to the Planet" (13 July 2006 New York Rev. Books) with assistance of Walter Simpson. "Gorilla" includes sidebars on 'Likely Consequences of Global Climate Change' and 'Three Policies Needed to Defuse the Global Warming Time Bomb'.

Usufruct. The deceit behind the attempts to discredit evidence of climate change reveals matters of importance. This deceit has a clear purpose: to confuse the public about the status of knowledge of global climate change, thus delaying effective action to mitigate climate change. The danger is that delay will cause tipping points to be passed, such that large climate impacts become inevitable, including the loss of all Arctic sea ice, destabilization of the West Antarctic ice sheet with disastrous sea level rise later this century, and extermination of a large fraction of animal and plant species (see "Dangerous", "Trace Gases", and "Gorilla" papers).

Make no doubt, however, if tipping points are passed, if we, in effect, destroy creation, passing on to our children, grandchildren, and the unborn a situation out of their control, the contrarians who work to deny and confuse will not be the principal culprits. The contrarians will be remembered as court jesters. There is no point to joust with court jesters. They will always be present. They will continue to entertain even if the Titanic begins to take on water. Their role and consequence is only as a diversion from what is important.

The real deal is this: the royalty controlling the court, the ones with the power, the ones with the ability to make a difference, with the ability to change our course, the ones who will live in infamy if we pass the tipping points, are the captains of industry, CEOs of EXXON/Mobil and fossil fuel leaders, automobile manufacturers, utilities, all of the leaders who have placed short-term profit above the fate of the planet and the well-being of our children. The court jesters are their jesters, occasionally paid for services, and more substantively supported by the captains' disinformation campaigns.

Court jesters serve as a distraction, a distraction from usufruct. Usufruct is the matter that the captains wish to deny, the matter that they do not want their children to know about. They realize that if there is no 'gorilla', than usufruct is not an important issue for them. So, with the help of jesters, they deny the existence of the gorilla. There is no danger of melting the Arctic, of destabilizing the West Antarctic ice sheet, of increasing hydrologic extremes, more droughts and stronger forest fires on the one hand and heavier downpours and floods on the other, threats to the fresh water supplies of huge numbers of people in different parts of the globe. "Whew! It is lucky that, as our jesters show, these are just imaginary concerns. We captains of industry can continue with business-as-usual, we do not need to face the tough problem of how to maintain profits without destroying our legacy in our children's eyes."

Usufruct is as American as the Declaration of Independence, implicit in the Preamble "...to ourselves and our Posterity...". It is explicitly discussed in a famous letter of 6 September

1789 from Thomas Jefferson to James Madison, discussing the proposed Bill of Rights to be added to the Constitution: "The question whether one generation of men has a right to bind another. . . is a question of such consequences as not only to merit decision, but place also among the fundamental principles of every government. . . . Thanks, Bob, I am writing something -- perhaps it can be used there, or modified to be used there.
Jim

At 01:52 PM 8/14/2007, Robert Cahalan wrote:

Jim,

Earlier I sent the following to Gavin -- and I realize that these are points you've been repeating for many years, just want to add that EarthObservatory could be helpful to get the word out:

Yes, I agree that this could be an educational opening for mainstream media.

My feeling is we need to lead with some of the faulty claims, and then illustrate that:

- (1) the data is all freely available and widely used for scientific study;
- (2) scientists use extensive statistical testing to determine whether observed differences can be ignored as being within the observational uncertainty or natural year-to-year variations;
- (3) changes of a given magnitude at a station or in a limited area average like the lower 48 contiguous United States, which covers about 2% Earth's surface, are less likely to be significant than a change of similar magnitude in averages over the full surface area of the Earth, which is less affected by many local influences (mention corrections to minimize urban effects too); and
- (4) changes in individual years, even ones that change the ranking of years, are less likely to be associated with sustained climate change than changes averaged over several successive years. On this last point we might quote the CCSP temperature synthesis and assessment product 1.1, which emphasized this point.

Of course these are all basic points that any of us climatologists know, but the public needs reminding, and this brouhaha could give

a good opportunity to educate any "fence-sitters" who might be listening...

.Bob.

On Aug 14, 2007, at 12:09 PM, David Herring wrote:

Thank you for clarifying, Gavin.

Dear Jim,

I know you're extremely busy, but I'm writing to request a little of your time in the near future to interview you for a short feature article on NASA's Earth Observatory that we would like to do about this issue. I'd like a little help in understanding more clearly how you conduct your analyses, what the nature of the "bug" was, and the fix that you put into place.

I have time late today (after 4 p.m.); any time after 11 a.m. tomorrow; any time before 3 p.m. on Thursday; and all day Friday. What could work for you? Also, any background reading material you care to send me / direct me to will help me to come better prepared with questions.

Best regards,

David Herring

Hi, Leslie.

I've attached the complete version of the interview, but this is the part I was looking for comment on. Basically, I'd just like to know if this is true and explanation of what really went on here.

Thanks!!!

Here it is:

McIntyre: I wrote to NASA in May and asked them for the source code for the adjustment software that they used to fix these stations and they refused to provide it. So I got interested in sort of looking at comparing the version of the temperature history of individual stations that NASA had against original data. I noticed that in some cases there was a very sharp jump in the differences between these two versions. The NASA version took a step in January 2000 relative to the original data. So, I then collected the data for both the NASA versions and the original data for all 1200 stations in the US historical network.

This led to a bit of fight with NASA in May because as I started downloading the data in sequence they cut off my access to the data.

Q. Meaning, your computer?
They blocked my IP address.

Q. Why were they so opposed?

Well, first of all they probably weren't used to, they don't have a very efficient distribution of the data so I ended up scraping the data off various web pages and I had written a computer program to do that. So, I was repetitively downloading data. Anyway, even after I was blocked and I explained myself they still didn't want to let me have access to the data. They just said go look at the original data. And I said no, I want to see the data you used. I know what the original data looks like. I want to see the data that you used. But one of the nice things about having a blog that gets a million and a half hits a month is that I then was able to publicize this block in real-time and they very quickly withdrew their position and allowed me to have access.

Steve McIntyre interview on August 15, 2007
Over the phone 4:30 pm

Q. Can you explain to me in layman's terms how you found this error?

Yeah. Quickly, a fellow in California named Anthony Watts noticed that some of the weather stations used to make historical U.S. statistics were located in places they weren't supposed to be. One of them was in a parking lot and the trend for the station in a parking lot was way up and a nearby station that was in a proper location in a rural area was relatively flat. So, this led to some controversy and he started a volunteer effort where people started surveying these weather stations and seeing what they looked like.

Now, defenders of the weather station system argued that NASA had software that could fix that data. And, so it really didn't matter if the station was in a parking lot in Tuscan or something like that. NASA software could fix it. So, that type of adjustment is a statistical issue that interests me. And, so I wrote to NASA in May and asked them for the source code for the adjustment software that they used to fix these stations and they refused to provide it. So I got interested in sort of looking at comparing the version of the temperature history of individual stations that NASA had against original data. I noticed that in some cases there was a very sharp jump in the differences between these two versions. The NASA version took a step in January 2000 relative to the original data. So, I then collected the data for both the NASA versions and the original data for all 1200 stations in the US historical network.

This led to a bit of fight with NASA in May because as I started downloading the data in sequence they cut off my access to the data.

Q. Meaning, your computer?
They blocked my IP address.

Q. Why were they so opposed?

Well, first of all they probably weren't used to, they don't have a very efficient distribution of the data so I ended up scraping the data off various web pages and I had written a computer program to do that. So, I was repetitively downloading data. Anyway, even after I was blocked and I explained myself they still didn't want to let me have access to the data. They just said go look at the original data. And I said no, I want to see the data you used. I know what the original data looks like. I want to see the data that you used. But one of the nice things about having a blog that gets a million and half hits a month is that I then was able to publicize this block in real-time and they very quickly withdrew their position and allowed me to have access.

Once they did that, I downloaded all 1200 stations and calculated the value of this step in the year 2000. In some cases it was a negative step and in some cases it was a positive step, but it became clear that what they had done they had, for some reason, changed the

version of data that they were using in 2000. Before 2000 they were using an adjusted version of data and after 2000 they were using an unadjusted version.

After the controversy broke out NASSA has said that the reason they did that was because the adjusted version was never available after 2000. That's actually untrue. The adjusted version is sitting in exactly the same data directory. It just seems to be an error of some kind on their part.

The amount on individual stations and this is where we started, trying to explain problems with individual stations, had jumps of up to one degree centigrade. I calculated a distribution of these jumps for all 1200 stations. Many of the jumps were negative, but the number of small jumps was itself only a fraction. Probably 75 percent of the stations had jumps of at least a quarter degree in the year 2000. But the average, because there both positive and negative ended up being somewhat over .15 degrees. That doesn't necessarily seem that much, but when the entire increase in temperature in the United States had been previously reported to be about half a degree, this .15 degree is not a small number when you are measuring half degree numbers.

So, I sent them an email notifying them of this error on Saturday August 4th and I pointed out that I thought they had changed data sources and on Tuesday August 7th they sent me a note agreeing that there was an error and they had, when I looked at their website, they had replaced the data for all 1200 U.S. historical weather stations and they'd also replaced their U.S. temperature history. While they added a mention of me on their webpage describing their methodology, but didn't provide any notice to readers that they had replaced all this data. So, for example, if you had been doing a study which required that you knew what the temperature was in Reno there was no notice that the data you'd had downloaded prior to August 2007 had contained an error. And in some cases a very large error.

When I looked at what their restated U.S. temperature history was, I noticed there as a change in the leading years. So, I wrote a light-hearted post on my blog that said there's a change in the leader board at the U.S. Open and that even though people thought that the years 1934 and the years 1998 had been in the clubhouse and had a shower, in fact they were still on the course and that 1934 had a late birdie and 1998 had a late bogie and 2006 had a late-triple bogie and when the dust settled 1934 was now the leader of the U.S. Open

Q. It seems at the heart of this was that NASA was unwilling to give you the methodology?

There are a couple of layers of issues. One issue was that they had an error. After I had identified this particular error to them and asked them for their source code so I could see how the rest of their adjustments actually worked, and this was really kind of an incidental point in checking their adjustment process. One of the things I started from was trying to evaluate whether their adjustment process was equal in adjusting bad data. One of the things I think you can conclude from this exercise is that their adjustment software was obviously incapable of picking up fictional jumps even as big as one

degree centigrade in the year 2000 and the proof was in the pudding because they hadn't picked it up. In fact, they hadn't only failed to fix it, they created it. So, the claim that they're adjustment methodology was capable of fixing bad data, I mean, that's the point I want people to take home from this. What they've done now is inserted a patch into an error that I identified for them but they haven't established that the rest of their adjustment methodology is any good. The adjustments are not small. The adjustments that they make are fully equal to the total amount of warming in the United States the past century. So, you're dealing with adjustments that are the same size as the effect that you are trying to measure. So, it's worth spending a minute or two trying to understand exactly what they did. Now, my interest in these things is understanding exactly what they did. Now, they're point of view is well, Gavin Schmidt of NASA says well "I don't get this audit mean." What he calls the audit mean. Well you know, everyone in the world, if you aren't an academic and you're doing business offerings or you work in a company, you get audited. And you can't say to an auditor, here are the invoices, you do your own financial statements if you don't like ours. Then, the auditor says my only interest how you did yours. So, when Gavid Schmidt says well you don't think we've done an adjustment methodology, why don't you do your own calculation and you can publish it, try to publish it in peer-reviewed literature and we can start from there. My take is well, I've had other experiences with folks like that before and then they think if you mis-implemented their methodology they scream to high heaven. So, I said "No" and they said "You are asking to be spoon-fed" and I said "No, I'm not asking to be spoon-fed." I'll deal with raw code, it's just that the verbal descriptions in academic articles do not meet the kind of engineering, quality level that I expect from things or that I am looking for and that represents one point of dispute between me and them. They don't seem to accept the idea. This is an important issue and therefore academics have to stop being precious and arguing that these codes are their private property.

Q. If NASA were to handle this all better, or to your liking, what are some recommendations you'd give them?

One of the main recommendations I've consistently made both to NASA and to journals is that when people publish articles they should have to archive the data as they used it. The exact providence of their data if they downloaded it from an internet archive they should have to post the URL of the place where they got the data and the date they downloaded it so you can know the exact version they got in case the versions change. And, they should archive the code in which they obtained the calculations. This is not by any means an impossible or far-fetched set of protocols. In econometrics right now, if you want to get an article published in the American Economic Review, a leading journal, that's exactly what you have to do. That policy was instituted by the then-editor who is now chairman of the federal reserve system. It's a policy that is easy to implement and there is a lot more riding right now on climate policy than there is on labor market studies or studies of inflation. So, I think there's every reason to require NASA and other contributors to climate science to improve their game in terms of how they provide disclosure to other readers and other researchers of their methodology and data.

In some cases there are some real problems. You know Lonnie Thompson the ice guy has published sort of summaries of his data which are mutually inconsistent and I've tried to get original sample data to try and reconcile these and he's refused and he's published articles in journals and the journals have refused to require him to do it and the National Science Foundation which has funded it has refused to require it so it's not just NASA it's a very widespread problem in climate science right now.

Subject: Question on GISS temperature data changing warmest year

From: "lesgiss@verizon.net" <lesgiss@verizon.net>

Date: Fri, 10 Aug 2007 11:00:44 -0400

To: jhansen@giss.nasa.gov, rruedy@giss.nasa.gov

Hi Jim:

Just left you a voice mail....you should have received an email inquiry from Charlie Lewis of the National Post newspaper in Canada asking for your comment and answer to some questions about new claims by Steve McIntyre that the GISS temperature data wrongly orders the warmest year on record...

Here's a story on the accusations:

<http://newsbusters.org/blogs/noel-sheppard/2007/08/09/did-media-or-nasa-withhold-climate-history-data-changes-public>

<http://www.dailytech.com/Blogger+finds+Y2K+bug+in+NASA+Climate+Data/article8383.htm>

Unfortunately, McIntyre's site, www.climateaudit.org, does not appear to be operational.

How do you wish to address this inquiry and any others that may come in??

Thanks.

Leslie

Steve McIntyre, of Toronto operates www.climateaudit.org and began to investigate the data and the methods used to arrive at the results that were graphed by NASA's Goddard Institute for Space Studies (GISS).

What he discovered was truly amazing. Since NASA does not fully publish the computer source code and formulae used to calculate the trends in the graph, nor the correction used to arrive at the 'corrected' data. He had to reverse engineer the process by comparing the raw data and the processed data..

Here is one of his first posts where he begins to understand what is happening. 'This imparts an upward discontinuity of a deg C in wintertime and 0.8 deg C annually. I checked the monthly data and determined that the discontinuity occurred on January 2000 - and, to that extent, appears to be a Y2K problem. I presume that this is a programming error.'

He further refines his argument showing the distribution of the error, and the problems with the USHCN temperature data. He also sends an email to NASA GISS advising of the problem.

He finally publishes it here, stating that NASA made a correction not only on their own web page, attributing the discovery to McIntyre, but NASA also issued a corrected set of temperature anomaly data which you can see here:

<http://data.giss.nasa.gov/qistemp/graphs/Fig.D.txt>

Steve McIntyre posted this data from NASA's newly published data set from Goddard Institute of Space Studies (GISS) These numbers represent deviation from the mean temperature calculated from temperature measurement stations throughout the USA.

According to the new data published by NASA, 1998 is no longer the hottest year ever. 1934 is.

Four of the top 10 years of US CONUS high temperature deviations are now from the 1930s: 1934, 1931, 1938 and 1939, while only 3 of the top 10 are from the last 10 years (1998, 2006, 1999). Several years (2000, 2002, 2003, 2004) fell well down the leaderboard, behind even 1900. (World rankings of temperature are calculated separately.)

Top 10 GISS U.S. Temperature deviation (deg C) in New Order 8/7/2007

Year	Old	New
1934	1.23	1.25
1998	1.24	1.23
1921	1.12	1.15
2006	1.23	1.13
1931	1.08	1.08
1999	0.94	0.93
1953	0.91	0.90
1990	0.88	0.87
1938	0.85	0.86
1939	0.84	0.85

Here's the old order of top 10 yearly temperatures.

Year	Old	New
1998	1.24	1.23
1934	1.23	1.25
2006	1.23	1.13
1921	1.12	1.15
1931	1.08	1.08
1999	0.94	0.93
1953	0.91	0.90
2001	0.90	0.76
1990	0.88	0.87
1938	0.85	0.86

I salute the work of Steven McIntyre, he has now made two major contributions to climate science.

- 1) Proving how the Mann 'hockey stick' used in all Gore's movie, An Inconvenient Truth, was based on unsupportable data and methods.
- 2) Proving how yearly temperature anomalies for the USA are based on data that had been processed incorrectly.

Dr. Roger Pielke of the University of Colorado also deserves credit because he was the one who encouraged me to pursue the www.surfacestations.org project due to his broad work on land use change and it's affect on regional and local climate.

Mr. McCarthy,

I read today that previous reports of the hottest years on record were not accurately reported and that

four of the top ten hottest years on record are from the 30s with 1934 as the hottest. Is this correct information and if so why isn't that noted on the web site?

Thanks for your help.

Hi Leslie,

Andy Revkin asked the same question and Jim's answer below says it all in the clearest and most beautiful way.

The blog you attached is a prime example of what gives bloggers a really bad name; somebody with no idea what he is talking about is spouting absolute nonsense, making no distinctions between what is essential (the facts he conveniently omits) and what is pure noise (which he is concentrating on exclusively).

He omits that the global mean time series (which is generally considered the standard measure for global warming) is unaffected

He concentrates on US time series which (US covering less than 2% of the world) is so noisy and has such a large margin of error that no conclusions can be drawn from it at this point; showing the plot of annual means before and after the correction would have made the whole article a joke since the differences are barely visible.

He had to use the device of ranking the years rather than showing the plots to make any point at all. The problem with rankings is that there are large clumps of years which are equal within the margin of error and rankings within these clumps are purely accidental.

He finds it astounding that years 1934 and 1998 reversed ranks, not remembering that the corrections only affected years 2000-2006, hence that there is no possible connection there.

By speaking of warmest year (rather than warmest year in the US time record) he successfully deceived people like Mark Taylor.

Reto

Hi Andy,

This seems to be a tempest inside somebody's teapot dome. One of the changes that we made in our analysis in 2001 was to include improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations ARE in the GHCN record, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in the records at those stations, some up, some down.

The net effect averaged over the U.S. was an error of about 0.15C or less in the post-2000 years, well within the uncertainty bar that we give. The effect on the global mean was of the order of a thousandths of a degree, i.e., entirely negligible.

It is unclear why anyone would try to make something out of this, perhaps a light not on upstairs? Or perhaps this is coming from one of the old contrarians? They can't seem to get over the fact that the real world has proven them to be full of malarkey! You would think that they would be ready to crawl under a rock by now!

Jim

(Reto, please correct if there is anything in the above that is not right.)

On 8/9/07, Andrew Revkin <anrevk@nytimes.com> wrote:
hi,

you probably noticed the mcintyre et al depiction of GISS annual temp estimates for US over time.

were the revisions published yet, or are they updated in databases alone?

also, are you doing same for global mean temp or is this specific issue related to US?

Subject: GISS - Truth driven vs agenda driven

Dear Leslie,

My fellow Canadians have unveiled another Global warming scam - yours!

Now that we know Mr. Hansen used incorrect data or procedures in determining the "hottest years", concluding that the top 5 warmest yeats since the 1890s are : 2005, 1998, 2002, 2003, 2006.

Yet, there on your website (<http://www.giss.nasa.gov/research/news/20070208/>) is the information still making what is now known to be a bogus claim.

Yes we are at a tipping point all right. And the truth is spilling all over your pro-AGW agenda.

Just like Mr. Manns infamous Hockey Stick graph, which was proven fraudulent by the same people who found your glaring errors, another lie bites the dust. Funny thing is, when they determined Mr. Mann was fudging things, they found that Mr. Mann's "peer reviewed" work was reviewed but not put through a rigourous, truth seeking, audit. That led to them forming climateaudit.org, to apply the audits that are so obviously missing from the process. And BINGO - Mr. Hansen is unmasked as a zealot.

Now, are you honestly a scientific driven institution, or will you admit to being an agenda driven one? I await the press conference to announce that you have had to revise the hottest years list. I await the update to your website to reflect the new, peer-audited, results. I await the confession that you made a huge mistake. I await the firing of those who created and flogged this lie.

Will you do the right thing?

Sincerely

Subject: another GISSTEMP inquiry

X-MIME-Autoconverted: from quoted-printable to 8bit by server2.giss.nasa.gov id I7DF1YF639425960

Hi Jim:

Two more calls of inquiry this morning on the GISSTEMP questions/changes:

1) Rob Gutro received a call from Daniel Dale of the Toronto Star (416-997-1169)

2) Steve Cole received a call from Richard Lofkin (he's not sure of the last name) of the Scotsman newspaper...working in Florida...his deadline is noon today...(954-755-5116)

Are you planning to issue any type of statement for the Friday inquiries or these??

Thanks.

Yes, if that's the case, it does seem like this kerfluffle is totally unrelated to the year-2000 correction. (Or at least, even if you had never fixed the bug, the new files posted in February 2008 would have caused a kerfluffle.)

Thank you so much for all your time.

Regards,
Keith

Subject: Revision to temp records?

Hi Leslie,

I saw this story in the Toronto Star today (<http://www6.lexisnexis.com/publisher/EndUser?Action=UserDisplayFullDocument&orgId=101937&topicId=106030004&docId=l:655133574>) and wanted to check its veracity.

I hadn't heard about a revision to NASA's temp readings that would make 1934 the hottest on record (rather than 1998). If there has been a revision, please point me in the right direction, so I can understand the new results and what changed.

Thanks,
Dan

Hi Jim:

See the question below about whether we need to put an editor's note on the data changes? Tabatha Thompson is an SMD PAO at HQ, Jason Townsend is the Acting GSFC webmaster while Lynn Jenner, the webmaster, Rob Gutro is Acting News Chief this week while Ed Campion is in Houston supporting the shuttle mission.

Please let me know.

Thanks.

Leslie

Leslie,

Do you know if the data appears in multiple locations? I don't know that
it warrants an editor's note. If I'm reading Dr. Hansen's note
correctly, the Washington Times post has very little substance. I'd be
interested in your thoughts.

Tabatha

Subject: Do we need an editor's note on GISS data web page?

Jason - This is a question for Tabatha at HQ - who would have to work
with Leslie McCarthy at NASA GISS, so I'm forwarding this question to
them.

Tabatha, Leslie- Do we need an editors Note (Using some of Jim's

response) on the webpage where the GISS data story appears?
Rob

Subject: Dr. Hansen available today

Hi Leslie, Just checking to see if Dr. Hansen is available to speak with Tom Moroney from our national radio program, "Simply Put" to discuss the revised climate data that shows 1934 as the hottest U.S. year on record, ousting 1998 as one of the hottest years. We can do this by phone this afternoon, Please let me know if he is available. Thank you

Subject: Interview request

Hello,

I'm following up on reports that NASA has adjusted its records for annual average temperatures over the past century. Would it be possible to arrange an interview for me with an expert from the Goddard Institute who could explain what happened, and what are the implications for climate change science.

I write for the CanWest newspaper chain in Canada representing 11 major daily newspapers across the country.

Thanks very much for your time,

Mike De Souza

another one? any takers?

How do you want to handle these requests today/the balance of the week????

Please let me know.

HQ PAO is asking whether you will be posting a clarification on the data changes. She reports that the webmaster indicated there was a lot of "interest" in this issue. Perhaps the paragraphs that Jim is writing for Jack Kaye/Don Anderson could be used as is or adapted? Please let me know ASAP so I can advise HQ..

Thanks.

To: lnolan@giss.nasa.gov

Subject: Media request (Brazil)

Dear Leslie Nolan,

I am a journalist from ÉPOCA, a weekly magazine in Brazil, and I would like to interview one spokesperson of Nasa about the changes in the data concerning average temperatures in the United States - which have changed the warmest year from 1998 to 1934.

I would like to talk to Mr. James Hansen but I have the idea of how he is busy and how my deadline is short (today, in fact). Then I would like to ask you for another researcher related to this issue. I have only one main question and it would be great to have Nasa's official position towards it:

- What is the meaning of the correction for global warming theory?

I hope you can help me with this simple request.

Thank you very much,

I look forward to hearing from you soon,

Best regards,

Leticia

That would be fine if Gavin is willing to do it. I am not taking any until I get something written, which may take most of the day. Of course, if there is a NY Times or Washington Post level, I might do that. Jim

Gavin--Jim says thanks if you can do this. I will have De Souza call you at home. He said he is writing a response today and thinks it may take him most of the day. He said that he would prefer only to handle major requests...will you be around for any others?

Also Lynn Chandler is hosting Josh Wolfe today at GSFC. She's referring to him as working on "your" project, "Illustrated Guide to Climate Change"....is it your project??

Thanks.

Hello,

I'm following up on reports that NASA has adjusted its records for annual average temperatures over the past century. Would it be possible to arrange an interview for me with an expert from the Goddard Institute who could explain what happened, and what are the implications for climate change science.

I write for the CanWest newspaper chain in Canada representing 11 major daily newspapers across the country.

Thanks very much for your time,

Mike De Souza

Dear Leslie Nolan,

I am a journalist from Época, a weekly magazine in Brazil, and I would like to interview one spokesperson of Nasa about the changes in the data concerning average temperatures in the United States - which have changed the warmest year from 1998 to 1934.

I would like to talk to Mr. James Hansen but I have the idea of how he is busy and how my deadline is short (today, in fact). Then I would like to ask you for another researcher related to this issue. I have only one main question and it would be great to have Nasa's

official

position towards it:

- What is the meaning of the correction for global warming theory?

I hope you can help me with this simple request.
Thank you very much,

I look forward to hearing from you soon,

Best regards,

Letícia

Here is my suggested revision:

Researchers at NASA's Goddard Institute for Space Studies in New York recently revised information on their global temperature record based on corrected data. The program that replaced for some US stations the 1880-1999 record by records that were adjusted for instrumentation and procedural changes, used the original source for the later years without modifying them to fit the adjusted data. The result was a discontinuity in year 2000 for the US stations involved. Since the necessary adjustment was positive for about half the stations and negative for the other half, the effect on US means was a discontinuity of +.15C, and of .003C for the global mean series. The researchers ...

Leslie,

As discussed a moment ago, here are my contact details at the Mail on Sunday.

00-44-207-938-7109 or 00-44-207-938-7400.

Cellphone

A couple of points I'd like to cover:

What is the likelihood that other countries (the UK, for example) are making similar statistical 'errors' in their temperature calculations?

Does NASA accept that the McIntyre controversy helps the cause of global warming 'sceptics'.

How can an organisation as powerful and well-resourced as NASA make such a mistake?

Thank you for your help.

Martin Delgado

Subject: FW: McIntyre Interview
Date: Thu, 16 Aug 2007 11:27:19 -0400

Hi to all:

Dr. McIntyre gave an interview to an organization called TownHall.com in which he alleges that NASA blocked his IP address and that because of 1.5 million hits/month on his website, NASA retreated from its position. She wants to know if this is an accurate retelling of what occurred?

The attachment is her ENTIRE 4 page interview which details in greater length the timeline and interactions with GISS....

Thanks.

Leslie

Subject: McIntyre Interview

Hi, Leslie.

I've attached the complete version of the interview, but this is the part I was looking for comment on. Basically, I'd just like to know if this is true and explanation of what really went on here.

Thanks!!!

Here it is:

McIntyre: I wrote to NASA in May and asked them for the source code for the adjustment software that they used to fix these stations and they refused to provide it. So I got interested in sort of looking at comparing the version of the temperature history of individual stations that NASA had against original data. I noticed that in some cases there was a very sharp jump in the differences between these two versions. The NASA version took a step in January 2000 relative to the original data. So, I then collected the data for both the NASA versions and the original data for all 1200

stages in the US historical network.

This led to a bit of fight with NASA in May because as I started downloading the data in sequence they cut off my access to the data.

Q. Meaning, your computer?
They blocked my IP address.

Q. Why were they so opposed?

Well, first of all they probably weren't used to, they don't have a very efficient distribution of the data so I ended up scraping the data off various web pages and I had written a computer program to do that. So, I was repetitively downloading data. Anyway, even after I was blocked and I explained myself they still didn't want to let me have access to the data. They just said go look at the original data. And I said no, I want to see the data you used. I know what the original data looks like. I want to see the data that you used. But one of the nice things about having a blog that gets a million and half hits a month is that I then was able to publicize this block in real-time and they very quickly withdrew their position and allowed me to have access.

Steve McIntyre interview on August 15, 20071.doc

Steve McIntyre interview on August 15, 2007
Over the phone 4:30 pm

Q. Can you explain to me in layman's terms how you found this error?

Yeah. Quickly, a fellow in California named Anthony Watts noticed that some of the weather stations used to make historical U.S. statistics were located in places they weren't supposed to be. One of them was in a parking lot and the trend for the station in a parking lot was way up and a nearby station that was in a proper location in a rural area was relatively flat. So, this led to some controversy and he started a volunteer effort where people started surveying these weather stations and seeing what they looked like.

Now, defenders of the weather station system argued that NASA had software that could fix that data. And, so it really didn't matter if the station was in a parking lot in Tuscan or something like that. NASA software could fix it. So, that type of adjustment is a statistical issue that interests me. And, so I wrote to NASA in May and asked them for the source code for the adjustment software that they used to fix these stations and they refused to provide it. So I got interested in sort of looking at comparing the version of the temperature history of individual stations that NASA had against original data. I noticed that in some cases there was a very sharp jump in the differences between these two versions. The NASA version took a step in January 2000 relative to the original data. So, I then collected the data for both the NASA versions and the original data for all 1200 stations in the US historical network.

This led to a bit of fight with NASA in May because as I started downloading the data in sequence they cut off my access to the data.

Q. Meaning, your computer?
They blocked my IP address.

Q. Why were they so opposed?

Well, first of all they probably weren't used to, they don't have a very efficient distribution of the data so I ended up scraping the data off various web pages and I had written a computer program to do that. So, I was repetitively downloading data. Anyway, even after I was blocked and I explained myself they still didn't want to let me have access to the data. They just said go look at the original data. And I said no, I want to see the data you used. I know what the original data looks like. I want to see the data that you used. But one of the nice things about having a blog that gets a million and half hits a month is that I then was able to publicize this block in real-time and they very quickly withdrew their position and allowed me to have access.

Once they did that, I downloaded all 1200 stations and calculated the value of this step in the year 2000. In some cases it was a negative step and in some cases it was a positive step, but it became clear that what they had done they had, for some reason, changed the

version of data that they were using in 2000. Before 2000 they were using an adjusted version of data and after 2000 they were using an unadjusted version.

After the controversy broke out NASSA has said that the reason they did that was because the adjusted version was never available after 2000. That's actually untrue. The adjusted version is sitting in exactly the same data directory. It just seems to be an error of some kind on their part.

The amount on individual stations and this is where we started, trying to explain problems with individual stations, had jumps of up to one degree centigrade. I calculated a distribution of these jumps for all 1200 stations. Many of the jumps were negative, but the number of small jumps was itself only a fraction. Probably 75 percent of the stations had jumps of at least a quarter degree in the year 2000. But the average, because there both positive and negative ended up being somewhat over .15 degrees. That doesn't necessarily seem that much, but when the entire increase in temperature in the United States had been previously reported to be about half a degree, this .15 degree is not a small number when you are measuring half degree numbers.

So, I sent them an email notifying them of this error on Saturday August 4th and I pointed out that I thought they had changed data sources and on Tuesday August 7th they sent me a note agreeing that there was an error and they had, when I looked at their website, they had replaced the data for all 1200 U.S. historical weather stations and they'd also replaced their U.S. temperature history. While they added a mention of me on their webpage describing their methodology, but didn't provide any notice to readers that they had replaced all this data. So, for example, if you had been doing a study which required that you knew what the temperature was in Reno there was no notice that the data you'd had downloaded prior to August 2007 had contained an error. And in some cases a very large error.

When I looked at what their restated U.S. temperature history was, I noticed there as a change in the leading years. So, I wrote a light-hearted post on my blog that said there's a change in the leader board at the U.S. Open and that even though people thought that the years 1934 and the years 1998 had been in the clubhouse and had a shower, in fact they were still on the course and that 1934 had a late birdie and 1998 had a late bogie and 2006 had a late-triple bogie and when the dust settled 1934 was now the leader of the U.S. Open

Q. It seems at the heart of this was that NASA was unwilling to give you the methodology?

There are a couple of layers of issues. One issue was that they had an error. After I had identified this particular error to them and asked them for their source code so I could see how the rest of their adjustments actually worked, and this was really kind of an incidental point in checking their adjustment process. One of the things I started from was trying to evaluate whether their adjustment process was equal in adjusting bad data. One of the things I think you can conclude from this exercise is that their adjustment software was obviously incapable of picking up fictional jumps even as big as one

degree centigrade in the year 2000 and the proof was in the pudding because they hadn't picked it up. In fact, they hadn't only failed to fix it, they created it. So, the claim that they're adjustment methodology was capable of fixing bad data, I mean, that's the point I want people to take home from this. What they've done now is inserted a patch into an error that I identified for them but they haven't established that the rest of their adjustment methodology is any good. The adjustments are not small. The adjustments that they make are fully equal to the total amount of warming in the United States the past century. So, you're dealing with adjustments that are the same size as the effect that you are trying to measure. So, it's worth spending a minute or two trying to understand exactly what they did. Now, my interest in these things is understanding exactly what they did. Now, they're point of view is well, Gavin Schmidt of NASA says well "I don't get this audit mean." What he calls the audit mean. Well you know, everyone in the world, if you aren't an academic and you're doing business offerings or you work in a company, you get audited. And you can't say to an auditor, here are the invoices, you do your own financial statements if you don't like ours. Then, the auditor says my only interest how you did yours. So, when Gavid Schmidt says well you don't think we've done an adjustment methodology, why don't you do your own calculation and you can publish it, try to publish it in peer-reviewed literature and we can start from there. My take is well, I've had other experiences with folks like that before and then they think if you mis-implemented their methodology they scream to high heaven. So, I said "No" and they said "You are asking to be spoon-fed" and I said "No, I'm not asking to be spoon-fed." I'll deal with raw code, it's just that the verbal descriptions in academic articles to not meet the kind of engineering, quality level that I expect from things or that I am looking for and that represents one point of dispute between me and them. They don't seem to accept the idea. This is an important issue and therefore academics have to stop being precious and arguing that these codes are their private property.

Q. If NASA were to handle this all better, or to your liking, what are some recommendations you'd give them?

One of the main recommendations I've consistently made both to NASA and to journals is that when people publish articles they should have to archive the data as they used it. The exact providence of their data if they downloaded it from an internet archive they should have to post the URL of the place where they got the data and the date they downloaded it so you can know the exact version they got in case the versions change. And, they should archive the code in which they obtained the calculations. This is not by any means an impossible or far-fetched set of protocols. In econometrics right now, if you want to get an article published in the American Economic Review, a leading journal, that's exactly what you have to do. That policy was instituted by the then-editor who is now chairman of the federal reserve system. It's a policy that is easy to implement and there is a lot more riding right now on climate policy than there is on labor market studies or studies of inflation. So, I think there's every reason to require NASA and other contributors to climate science to improve their game in terms of how they provide disclosure to other readers and other researchers of their methodology and data.

In some cases there are some real problems. You know Lonnie Thompson the ice guy has published sort of summaries of his data which are mutually inconsistent and I've tried to get original sample data to try and reconcile these and he's refused and he's published articles in journals and the journals have refused to require him to do it and the National Science Foundation which has funded it has refused to require it so it's not just NASA it's a very widespread problem in climate science right now.

Subject: Re: [Fwd: Re: FW: Per our Discussion - Note for Web Site]

So here is an attempt to put the pieces together; I also adjusted the beginning and end to fit the other modifications; please don't hesitate to further improve my style:

Researchers at NASA's Goddard Institute for Space Studies in New York recently revised information on their global temperature record after correcting a step in their data acquisition procedure. That process appropriately replaced some US station records with records adjusted for instrumental and procedural changes. However, it reverted to the unadjusted data after 1999, the last year for which the adjusted data were available. This resulted in a discontinuity in year 2000 for the US stations involved. The necessary adjustments turned out to be positive for about half the stations and negative for the other half, so the effect was reduced to a jump of +.15C for the US means, and a jump of +.003C for the global means, well within the margin of error. The researchers corrected the computer program and posted their revised data. More information is available here: (LINK TO GISS SITE).

Hi Reto:

Please verify this final version is okay:

Researchers at NASA's Goddard Institute for Space Studies in New York recently revised their global temperature record after correcting a step in their data acquisition procedure. The prior process appropriately replaced some US station records with records adjusted for instrumental and procedural changes. However, it reverted to the unadjusted data after 1999, the last year for which the adjusted data were available. This resulted in a discontinuity in year 2000 for the US stations involved. The adjustments necessary to remove the discontinuity turned out to be positive for about half the stations and negative for the other half. The net effect of the prior flaw was to increase the mean US temperature by about 0.15C and global temperature by about 0.003C, changes that were within the margin of error. The researchers corrected the computer program and posted their revised data on 7 August 2007. More information is available here: (LINK TO GISS SITE).

Thanks.

Subject: McIntyre Interview

Hi, Leslie.

I've attached the complete version of the interview, but this is the part I was looking for comment on. Basically, I'd just like to know if this is true and explanation of what really went on here.

Thanks!!!

Here it is:

McIntyre:I wrote to NASA in May and asked them for the source code for the adjustment software that they used to fix these stations and they refused to provide it. So I got interested in sort of looking at comparing the version of the temperature history of individual stations that NASA had against original data. I noticed that in some cases there was a very sharp jump in the differences between these two versions. The NASA version took a step in January 2000 relative to the original data. So, I then collected the data for both the NASA versions and the original data for all 1200 stages in the US historical network.

This led to a bit of fight with NASA in May because as I started downloading the data in sequence they cut off my access to the data.

Q. Meaning, your computer?
They blocked my IP address.

Q. Why were they so opposed?

Well, first of all they probably weren't used to, they don't have a very efficient distribution of the data so I ended up scraping the data off various web pages and I had written a computer program to do that. So, I was repetitively downloading data. Anyway, even after I was blocked and I

explained myself they still didn't want to let me have access to the data. They just said go look at the original data. And I said no, I want to see the data you used. I know what the original data looks like. I want to see the data that you used. But one of the nice things about having a blog that gets a million and half hits a month is that I then was able to publicize this block in real-time and they very quickly withdrew their position and allowed me to have access.

Content-Encoding: base64

Steve McIntyre interview on August 15, 2007
Over the phone 4:30 pm

Q. Can you explain to me in layman's terms how you found this error?

Yeah. Quickly, a fellow in California named Anthony Watts noticed that some of the weather stations used to make historical U.S. statistics were located in places they weren't supposed to be. One of them was in a parking lot and the trend for the station in a parking lot was way up and a nearby station that was in a proper location in a rural area was relatively flat. So, this led to some controversy and he started a volunteer effort where people started surveying these weather stations and seeing what they looked like.

Now, defenders of the weather station system argued that NASA had software that could fix that data. And, so it really didn't matter if the station was in a parking lot in Tuscan or something like that. NASA software could fix it. So, that type of adjustment is a statistical issue that interests me. And, so I wrote to NASA in May and asked them for the source code for the adjustment software that they used to fix these stations and they refused to provide it. So I got interested in sort of looking at comparing the version of the temperature history of individual stations that NASA had against original data. I noticed that in some cases there was a very sharp jump in the differences between these two versions. The NASA version took a step in January 2000 relative to the original data. So, I then collected the data for both the NASA versions and the original data for all 1200 stations in the US historical network.

This led to a bit of fight with NASA in May because as I started downloading the data in sequence they cut off my access to the data.

Q. Meaning, your computer?
They blocked my IP address.

Q. Why were they so opposed?

Well, first of all they probably weren't used to, they don't have a very efficient distribution of the data so I ended up scraping the data off various web pages and I had written a computer program to do that. So, I was repetitively downloading data. Anyway, even after I was blocked and I explained myself they still didn't want to let me have access to the data. They just said go look at the original data. And I said no, I want to see the data you used. I know what the original data looks like. I want to see the data that you used. But one of the nice things about having a blog that gets a million and half hits a month is that I then was able to publicize this block in real-time and they very quickly withdrew their position and allowed me to have access.

Once they did that, I downloaded all 1200 stations and calculated the value of this step in the year 2000. In some cases it was a negative step and in some cases it was a positive step, but it became clear that what they had done they had, for some reason, changed the

version of data that they were using in 2000. Before 2000 they were using an adjusted version of data and after 2000 they were using an unadjusted version.

After the controversy broke out NASSA has said that the reason they did that was because the adjusted version was never available after 2000. That's actually untrue. The adjusted version is sitting in exactly the same data directory. It just seems to be an error of some kind on their part.

The amount on individual stations and this is where we started, trying to explain problems with individual stations, had jumps of up to one degree centigrade. I calculated a distribution of these jumps for all 1200 stations. Many of the jumps were negative, but the number of small jumps was itself only a fraction. Probably 75 percent of the stations had jumps of at least a quarter degree in the year 2000. But the average, because there both positive and negative ended up being somewhat over .15 degrees. That doesn't necessarily seem that much, but when the entire increase in temperature in the United States had been previously reported to be about half a degree, this .15 degree is not a small number when you are measuring half degree numbers.

So, I sent them an email notifying them of this error on Saturday August 4th and I pointed out that I thought they had changed data sources and on Tuesday August 7th they sent me a note agreeing that there was an error and they had, when I looked at their website, they had replaced the data for all 1200 U.S. historical weather stations and they'd also replaced their U.S. temperature history. While they added a mention of me on their webpage describing their methodology, but didn't provide any notice to readers that they had replaced all this data. So, for example, if you had been doing a study which required that you knew what the temperature was in Reno there was no notice that the data you'd had downloaded prior to August 2007 had contained an error. And in some cases a very large error.

When I looked at what their restated U.S. temperature history was, I noticed there as a change in the leading years. So, I wrote a light-hearted post on my blog that said there's a change in the leader board at the U.S. Open and that even though people thought that the years 1934 and the years 1998 had been in the clubhouse and had a shower, in fact they were still on the course and that 1934 had a late birdie and 1998 had a late bogie and 2006 had a late-triple bogie and when the dust settled 1934 was now the leader of the U.S. Open

Q. It seems at the heart of this was that NASA was unwilling to give you the methodology?

There are a couple of layers of issues. One issue was that they had an error. After I had identified this particular error to them and asked them for their source code so I could see how the rest of their adjustments actually worked, and this was really kind of an incidental point in checking their adjustment process. One of the things I started from was trying to evaluate whether their adjustment process was equal in adjusting bad data. One of the things I think you can conclude from this exercise is that their adjustment software was obviously incapable of picking up fictional jumps even as big as one

degree centigrade in the year 2000 and the proof was in the pudding because they hadn't picked it up. In fact, they hadn't only failed to fix it, they created it. So, the claim that they're adjustment methodology was capable of fixing bad data, I mean, that's the point I want people to take home from this. What they've done now is inserted a patch into an error that I identified for them but they haven't established that the rest of their adjustment methodology is any good. The adjustments are not small. The adjustments that they make are fully equal to the total amount of warming in the United States the past century. So, you're dealing with adjustments that are the same size as the effect that you are trying to measure. So, it's worth spending a minute or two trying to understand exactly what they did. Now, my interest in these things is understanding exactly what they did. Now, they're point of view is well, Gavin Schmidt of NASA says well "I don't get this audit mean." What he calls the audit mean. Well you know, everyone in the world, if you aren't an academic and you're doing business offerings or you work in a company, you get audited. And you can't say to an auditor, here are the invoices, you do your own financial statements if you don't like ours. Then, the auditor says my only interest how you did yours. So, when Gavid Schmidt says well you don't think we've done an adjustment methodology, why don't you do your own calculation and you can publish it, try to publish it in peer-reviewed literature and we can start from there. My take is well, I've had other experiences with folks like that before and then they think if you mis-implemented their methodology they scream to high heaven. So, I said "No" and they said "You are asking to be spoon-fed" and I said "No, I'm not asking to be spoon-fed." I'll deal with raw code, it's just that the verbal descriptions in academic articles to not meet the kind of engineering, quality level that I expect from things or that I am looking for and that represents one point of dispute between me and them. They don't seem to accept the idea. This is an important issue and therefore academics have to stop being precious and arguing that these codes are their private property.

Q. If NASA were to handle this all better, or to your liking, what are some recommendations you'd give them?

One of the main recommendations I've consistently made both to NASA and to journals is that when people publish articles they should have to archive the data as they used it. The exact providence of their data if they downloaded it from an internet archive they should have to post the URL of the place where they got the data and the date they downloaded it so you can know the exact version they got in case the versions change. And, they should archive the code in which they obtained the calculations. This is not by any means an impossible or far-fetched set of protocols. In econometrics right now, if you want to get an article published in the American Economic Review, a leading journal, that's exactly what you have to do. That policy was instituted by the then-editor who is now chairman of the federal reserve system. It's a policy that is easy to implement and there is a lot more riding right now on climate policy than there is on labor market studies or studies of inflation. So, I think there's every reason to require NASA and other contributors to climate science to improve their game in terms of how they provide disclosure to other readers and other researchers of their methodology and data.

Subject: draft McIntyre statement

From: "lesgiss@verizon.net" <lesgiss@verizon.net>

Date: Thu, 16 Aug 2007 12:20:00 -0400

To: rruedy@giss.nasa.gov

Hi Reto:

I have not heard from Jim about the McIntyre allegations of cutting off his IP address...but drafted this short response...what do you think???

On May 16, 2007, an IP address attached to a cable.rogers.com network made 16,000 attempts in several hours to scrape GISTEMP station data. The webmaster had noted that this large volume was dramatically slowing access to the site and data by other users. That address was blocked by the GISS webmaster as it violated rules from using web robots to access off-limits directories. The webmaster had no idea of the identity of the user until Dr. McIntyre emailed the webmaster. He was then advised of the reason for his service denial and advised to contact the GISTEMP research group to explain data needs. On the 17th, Dr. McIntyre again inquired about his access and was again advised to contact the GISTEMP group. Dr. Reto Ruedy of the GISTEMP group contacted Dr. McIntyre to discuss his requests.

(need to add in details about his requests to provide data and/or in a format that we don't have-Reto??)

Shortly after that email exchange, Dr. McIntyre was advised that he could again begin downloading provided that he accepted generally accepted protocols, i.e. doing so at times so as to not adversely affect other users (late nights, weekends, etc.).

Thank you for this. I will observe this condition.

I realize that you have provided some documentation of what you did. In econometrics, it is a condition of publication in journals that authors archive their code and data so that their results can be routinely replicated. I realize that no such standards apply to climate science. However, equally, there is no prohibition on individual climate scientists voluntarily adopting these best practice standards. In that spirit, I would appreciate it if I could inspect the code used to process the GHCN data. Thanks, Steve McIntyre

Subject: RE: Access to GISTEMP

After a short meeting with Dr. Hansen, we were advised to let you download whatever you want as long as generally accepted protocols are observed. Please try to do so at a time that does not impact other users, i.e. late nights, weekends.

What we did with the GHCN data is carefully documented in the publications listed on our website. We are not creating an alternate version of the GHCN data, we are mainly combining their data in various steps to create our anomaly maps.

Sincerely,

Reto A. Ruedy

On Thu, 2007-05-17 at 16:37 -0400, Steve McIntyre wrote:

In answer to your question, I'm interested in the data as it is presented to the public. All I was doing was downloading the data that is supposedly available to the public, but in a way that would not take

4 weeks of manual labor. If your version differs from the GHCN version,

I'm interested in downloading your version so that I can assess the differences.

Subject: RE: Access to GISTEMP

Dear Steve,

Our main focus working with observed data is creating a gridded set of temperature anomalies which gives reasonable means over comparatively large regions - the global mean average being one of the major goals.

If

you are interested in individual stations, you are much better off working directly with the GHCN data.

Our station data are really intermediate steps to obtain a global anomaly map, and are not to be viewed as an end result. A modified time

series for a particular location may be more representative for the surrounding region than for that particular location. So it is important

to use these data in the proper context.

All our publications and investigations deal with regional temperature anomalies and that is the only use these data are good for after our modifications.

If you still think that downloading our "scratch pads" is important to your investigations, please let me know exactly what stage after the raw

GHCN data you need and maybe an indication why you need it, and I'll try

to provide you with the necessary data.

Again, we are not trying to compete with GHCN as provider of station data; we are using their data for a very specific project and we made

perhaps unwisely - some of our tools that we used to test the various steps of our process available on the web.

Reto

On Thu, 2007-05-17 at 15:18 -0400, Steve McIntyre wrote:

I know how to use the GHCN data. I'm not interested in "tips" on how to use it.

I'm interested in the versions as used by GISS. The GHCN version is convenient to download and I see no reason why GISS versions should not be available on equivalent terms.

To: Steve McIntyre
Subject: Re: Access to GISTEMP

Please contact the GISTEMP group and inquire if they are willing to provide you with the dataset(s) from which the website applications extract information.

If they are not (I do not know what their current policy on this), then you can go a step closer to the source and obtain station data from the same location that the GISTEMP group obtains the original "raw" datasets that they work from. That is the Global Historical Climatology Network at <http://www.ncdc.noaa.gov/oa/climate/ghcn-monthly/index.php>

I'm not sure which specific files from the GHCN site are used. But if the complete GISTEMP data are not available then perhaps Dr. Ruedy of the GISTEMP group could give you some tips on how to use the GHCN data.

Steve,

Although you did not provide any further details about your problem, I will assume that you are the person on the cable.rogers.com network who has been running a robot for the past several hours trying to scrape GISTEMP station data and who has made over 16000 (!) requests to the data.giss.nasa.gov website.

Please note that the robots.txt file on that website includes a list of directories which any legitimate web robot is forbidden from trying to index. That list of off-limits directories includes the /work/ and /cgi-bin/ directories.

Because the robot running on the cable.rogers.com network has rather obviously and blatantly violated those rules, I placed a block on our server restricting its access to the server.

If you are indeed the person who has been running that particular web robot, and if you do need access to some large amount of the GISTEMP station data for a scientific purpose, then you should contact the GISTEMP research group to explain your needs. E-mail addresses for the GISTEMP research group are located at the bottom of the page at <http://data.giss.nasa.gov/gistemp/>

Jim's email just came in - he changed one sentence (obviously he did not like my "jumps") - fine with me.

Below is the whole interaction as far as access questions are concerned.

Thank you for this. I will observe this condition.

I realize that you have provided some documentation of what you did. In econometrics, it is a condition of publication in journals that authors archive their code and data so that their results can be routinely replicated. I realize that no such standards apply to climate science. However, equally, there is no prohibition on individual climate scientists voluntarily adopting these best practice standards. In that spirit, I would appreciate it if I could inspect the code used to process the GHCN data. Thanks, Steve McIntyre

Subject: RE: Access to GISTEMP

After a short meeting with Dr. Hansen, we were advised to let you download whatever you want as long as generally accepted protocols are observed. Please try to do so at a time that does not impact other users, i.e. late nights, weekends.

What we did with the GHCN data is carefully documented in the publications listed on our website. We are not creating an alternate version of the GHCN data, we are mainly combining their data in various steps to create our anomaly maps.

Sincerely,

Reto A. Ruedy

On Thu, 2007-05-17 at 16:37 -0400, Steve McIntyre wrote:

In answer to your question, I'm interested in the data as it is presented to the public. All I was doing was downloading the data that is supposedly available to the public, but in a way that would not take

4 weeks of manual labor. If your version differs from the GHCN version,

I'm interested in downloading your version so that I can assess the differences.

Subject: RE: Access to GISTEMP

Dear Steve,

Our main focus working with observed data is creating a gridded set of temperature anomalies which gives reasonable means over comparatively large regions - the global mean average being one of the major goals.

If

you are interested in individual stations, you are much better off working directly with the GHCN data.

Our station data are really intermediate steps to obtain a global anomaly map, and are not to be viewed as an end result. A modified time

series for a particular location may be more representative for the surrounding region than for that particular location. So it is important

to use these data in the proper context.

All our publications and investigations deal with regional temperature anomalies and that is the only use these data are good for after our modifications.

If you still think that downloading our "scratch pads" is important to your investigations, please let me know exactly what stage after the raw

GHCN data you need and maybe an indication why you need it, and I'll try

to provide you with the necessary data.

Again, we are not trying to compete with GHCN as provider of station data; we are using their data for a very specific project and we made

perhaps unwisely - some of our tools that we used to test the various steps of our process available on the web.

Reto

On Thu, 2007-05-17 at 15:18 -0400, Steve McIntyre wrote:

I know how to use the GHCN data. I'm not interested in "tips" on how to use it.

I'm interested in the versions as used by GISS. The GHCN version is convenient to download and I see no reason why GISS versions should not be available on equivalent terms.

Subject: Re: Access to GISTEMP

Please contact the GISTEMP group and inquire if they are willing to provide you with the dataset(s) from which the website applications extract information.

If they are not (I do not know what their current policy on this), then you can go a step closer to the source and obtain station data from the same location that the GISTEMP group obtains the original "raw" datasets that they work from. That is the Global Historical Climatology Network at <http://www.ncdc.noaa.gov/oa/climate/ghcn-monthly/index.php>

I'm not sure which specific files from the GHCN site are used. But if the complete GISTEMP data are not available then perhaps Dr. Ruedy of the GISTEMP group could give you some tips on how to use the GHCN data.

I am blocked from access to the page where the email addresses are

located.

Good point. That was foolish of me to suggest checking a

page on which access had been turned off.

I have turned off the restriction that I added to the server on data.giss.nasa.gov last night so that you can access the GISTEMP page and view the contact information.

I have been attempting to collate station data for scientific purposes.

I have not been running a robot but have been running a program

in
R

that collects station data.

It is an automated process scraping content from the website, and if that isn't what a web robot does, then it's close enough.

Steve,

Although you did not provide any further details about your problem, I will assume that you are the person on the cable.rogers.com network who has been running a robot for the past several hours trying to scrape GISTEMP station data and who has made over 16000 (!) requests to the data.giss.nasa.gov website.

Please note that the robots.txt file on that website includes a list of directories which any legitimate web robot is forbidden from trying to index. That list of off-limits directories includes the /work/ and /cgi-bin/ directories.

Because the robot running on the cable.rogers.com network has rather obviously and blatantly violated those rules, I placed a block on our server restricting its access to the server.

If you are indeed the person who has been running that particular web robot, and if you do need access to some large amount of the GISTEMP station data for a scientific purpose, then you should contact the GISTEMP research group to explain your needs. E-mail addresses for the GISTEMP research group are located at the bottom of the page at <http://data.giss.nasa.gov/gistemp/>

the issue is here that you are dealing with a hostile interviewer. In such circumstances, it is much better simply to point out clear errors. If you open up another front they will dive on that instead and abandon all the previous positions (since they are not sincere in any case).

It does however highlight the rhetorical power of saying that the code is secret and things are being kept from the public. It may still be worth putting up a clean version of the adjustment program on the website in order to have something to point to in such cases.

gavin

On Thu, 2007-08-16 at 18:08, Reto Ruedy wrote:

Gavin,

So you don't think it is worth to point out that the whole first part of the interview section below is a total fabrication, and his first request for source code came with the "thank you" note mentioned at the end of the response, still May 17. Also, his reasons for our "reluctance" is wild speculation that is light years away from reality.

On second thought, it's not worth going into these details, especially in a case where the interviewer is more likely to believe Steve than us.

So, I'm fine with the edits.

Hi Tabatha:

Received a call from this reporter yesterday from TownHall.com seeking NASA comment on whether Steve McIntyre was blocked from retrieving NASA data. I did tell her at the end of the work day we were still working a statement (it had been approved by Reto Ruedy and Gavin Schmidt, but not yet by Jim Hansen)...

http://www.townhall.com/Columnists/AmandaCarpenter/2007/08/17/nasa_blocked_climate_change_blogger_from_data?page=full&comments=true

His IP address was blocked for HUGE volume of hits...without the webmaster having any idea who he was. Within a day, in an exchange of emails about clarification over his needs, he was restored. This was a routine denial of service, as the webmaster has done with others in the past.... Its spelled out in a bit more detail in the statement...

Thanks.

Subject: BBC TV series

Dear Lesley,

I am a researcher from the BBC, in the UK. I am developing a landmark television series, looking at the effects of artificial chemicals (all things toxic!) on our environment on a global scale. It will be the ultimate global health check - an update on where we stand now, 45 years since Rachel Carson wrote her influential and controversial book Silent Spring. Using similar headings as Carson for the chapters in her book, the six episodes will be as follows:

Planet
Oceans (and Rivers)
Humans
Insects, Soils and Funghi
Animals, Birds & Fish
Our Green Mantle (trees, plants etc)

Regarding the first episode, "Planet", I am keen to speak to NASA scientists who are using satellites to measure atmospheric pollution from space. Your colleague Rob, in the Goddard media relations office, has recommended four scientists, who you may be able to put me in touch with:

James Hansen
Drew Schindel
Gavin Schmidt
Reto Reudy

I am keen to get a clear and informed idea of how the Earth has changed in the past four decades, how NASA is measuring these changes, and how we could illustrate these changes in a TV programme in the future. Also, I would like to know about any new and positive developments where chemicals which have been a problem in the

atmosphere have been remedied by new and advanced methods?

I look forward to hearing from you.

Kind regards,

James

Headline: Change in hottest year fuels global warming skeptics

Byline: Brad Knickerbocker

Date: 08/23/2007

- Was 1998 the hottest year in United States history, as most reporting on climate change has presumed? Or was that record set back in 1934 before "global warming" became a scary household phrase?

A corrective tweak to National Aeronautics and Space Administration's formulation shows that the hottest year on record in the US indeed was back during the Dust Bowl days.

But does this mean that all the concern about global warming being a relatively recent phenomenon tied to carbon-belching power plants and hulking SUVs is a bunch of Al Gore hooey?

Climate change skeptics and their cheering section among conservative bloggers and radio shoutmeisters think so ◆ even though most

scientists say, no, the tweak is not a big deal and overall trends are in the direction of toastier days around the globe.

The controversy began "when Steve McIntyre of the blog Climateaudit.org e-mailed NASA scientists pointing out an unusual jump in temperature data from 1999 to 2000," reports The Los Angeles Times.

"When researchers checked, they found that the agency had merged two data sets that had been incorrectly assumed to match. When the data were corrected, it resulted in a decrease of 0.27 degrees Fahrenheit in yearly temperatures since 2000 and a smaller decrease in earlier years. That meant that 1998, which had been 0.02 degrees warmer than 1934, was now 0.04 degrees cooler."

Put another way, the new figures show that 4 of the 10 warmest years in the US occurred during the 1930s, not more recently. This caused a stir among those critical of the push to stem human-induced climate change.

"Conservative radio talk show host Rush Limbaugh used reports of the revisions to argue that climate change is a hoax perpetrated by

scientists with liberal agendas," reported The Washington Post.

"We have proof of man-made global warming," Limbaugh said on his show♦. "The man-made global warming is inside NASA. The man-made global warming is in the scientific community with false data."

Blogger Steve McIntyre, who started the controversy, lives in Canada. His hometown newspaper, The Toronto Star, headlined its story "Red faces at NASA over climate-change blunder."

"They moved pretty fast on this," McIntyre said. "There must have been some long faces."

Still, McIntyre called his finding "a micro-change," and others agree. For one, the reranking didn't affect global records, and 1998 remains tied with 2005 as the hottest year on record, the Los Angeles Times notes, quoting climatologist Gavin Schmidt of NASA's Goddard Institute for Space Studies in New York.

"The data adjustment changes 'the inconsequential bragging rights for certain years in the U.S.," he said. But 'global warming is a global issue, and the global numbers show that there is no question that the last five to 10 years have been the hottest period of the last century.' "

A main target of criticism over the data shift is James Hansen, director of the Goddard Institute at NASA and a frequently quoted expert on climate change. On his website, Dr. Hansen explained the reasons for the change, and he played down its importance.

"How big an error did this flaw cause?... The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect ... on the global warming issue? Certainly not♦. What we

have here is a case of ... contrarians who present results in ways intended to deceive the public into believing that the changes have greater significance than reality. They aim to make a mountain out of a mole hill."

Meanwhile, evidence of global warming continues to mount. Citing a new study by researchers at the University of East Anglia, The Guardian newspaper reports that "some tipping points for climate change could be closer than previously thought."

"In drawing together research on tipping points, where damage due to climate change occurs irreversibly and at an increasing rate, the researchers concluded that the risks were much greater than those predicted by the latest report by the Intergovernmental Panel on Climate Change (IPCC)."

Is the issue settled? Far from it, says Roy Spencer, a principal research scientist for the University of Alabama, who describes himself as "skeptical of the claim that global warming is mostly manmade."

Blogging on TCSDaily.com Dr. Spencer writes:

"In case you hadn't noticed, the global warming debate has now escalated from a minor skirmish to an all-out war♦. In the last year or so, more and more scientists have been coming out of the closet

commended: "Change in hottest year fuels global warming skeptics"

and admitting they've had some doubts about this whole global warming thing."

Subject: Question about Warmest year

Hello Ms. McCarthy,

I'm with the science centre in Calgary, Canada and am looking for some authoritative and quotable information on what Goddard researchers have measured as the warmest years in the last century. The information I have from Goddard press releases such as at:

http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html

is that 2005, 1998, 2002, 2003 and 2006 are the warmest years of the last 100 years.

However, a columnist for a local newspaper in an August 24 editorial denying global warming and Arctic ice reduction quotes Goddard research as saying this:

NASA's Goddard Institute for Space Studies had to back down from its previous claim that 1998 was the U.S.'s hottest year on record. That distinction now goes to 1934.

Indeed, four of the hottest years on record are in the 1930s and polar bears survived just fine.

Before I counter with any rebuttal or letter to the editor I wanted to check what might be the source of that "fact" attributed to Goddard research and how the writer might have misconstrued some statement out of Goddard. I'm looking for a quote I can include in my rebuttal and even a reference to some published paper that provides an authoritative answer to the question of "what were the warmest years."

Many thanks for your time.

Alan Dyer
Producer and Astronomer
TELUS World of Science

Hi:

Had a voice mail today from Neil Monroe of the National Journal (202-739-8464) who is writing what he called a "small blurb" on the temperature data changes. He would like to speak with someone today if possible.

<http://nationaljournal.com/>

Please advise.

Thanks.

Leslie

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the *Washington Times* (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and

: <no subject>

Space Administration? Well, he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Interesting papers. Has there been any attempt to use Bayesian forecasting techniques on the temperature record? For other reasons I got off into looking at Pole, West, and Harrison's "Applied Bayesian Forecasting and Time Series Analysis" [1994, Chapman and Hall].

While the theories promoting "Global Warming" are plausible, so far, the scientific data do not support them.

That's why the environmental activists now call it "Climate Change." Any deviation in precipitation or temperature from the average must be caused by Republicans driving SUVs.

For those of us who live in New England, global warming occurred 12 thousand years ago. Whenever I work in my garden or on my lawn, I have to deal with the rocks left behind by the glaciers.

As a nation, our highest priorities need to be to win the War on Terror and to prepare for the coming World War.

Unfortunately, as always, the left is trying to distract us from THIS "inconvenient truth."

At 10:21 AM 8/29/07,

@ajg.com wrote:

Good Morning Mr. Hansen,

Today's Wall Street Journal has an article on page A14 titled, Not So Hot. Stephen McIntyre found that NASA made a technical error in standardizing the weather air temperature data post 2000. Curiously and most interesting is that these temperature mistakes were only for the United States; their net effect was to lower the average temperature reading from 2000-2006 by 0.15C.

It is interesting that Mr. Hansen has been unapologetic about NASA's error. I don't see the point of getting excited about global warming, if NASA's chief is going to ignore its error and continue about the global warming issue, when this article explicitly shows that 1934 was the warmest year on record. Ignoring facts is not very scientific; I hope that Mr. Hansen does not call himself a scientist, since he chooses to ignore truth along with Al Gore.

ears of bad data corrected; 1998 no longer the warmest year on record

To: James.E.Hansen@nasa.gov

Dear Dr. Hansen,

I'm doing some research on anthropological global warming. The problem I'm having now is that NASA has now released corrected figures, and the changes are truly astounding. The warmest year on record is now 1934. 1998 (long referred to as record-breaking) moves to second place. 1921 takes third. In fact, 5 of the 10 warmest years on record now **all occur before World War II**. This change leads me to believe NASA is being manipulated by those who "deny" the globe is in a warming trend. Could you please help me understand these revelations? Thank you and have a nice day.

Sincerely,

Leslie,

As discussed a moment ago, here are my contact details at the Mail on Sunday.

00-44-207-938-7109 or 00-44-207-938-7400.

A couple of points I'd like to cover:

What is the likelihood that other countries (the UK, for example) are making similar statistical 'errors' in their temperature calculations?

Does NASA accept that the McIntyre controversy helps the cause of global warming 'sceptics'.

How can an organisation as powerful and well-resourced as NASA make such a mistake?

Thank you for your help.

Martin Delgado

To: jhansen@giss.nasa.gov

Leemans and Eickhout (2004) found that ecosystem adaptive capacity decreases rapidly with an increasing rate of climate change.

If the rate should exceed 0.4 C/decade, all ecosystems will be quickly destroyed.

According to the Intergovernmental Panel on Climate Change (IPCC), the global average temperature today is increasing by 0.2 C/decade.

This increase is caused by greenhouse gases we put into the atmosphere decades ago, due to the lag time between emission and temperature rise.

We have emitted nearly double the greenhouse gas since then, and are increasing our emissions at a rate of over 3% per year.

Therefore, in the next couple of decades we are facing the quick destruction of all the world's ecosystems, which will result in abrupt climate change (I suggest reading the Pentagon's alarming report on this subject).

Reference: Leemans og Eickhout, 2004, Another reason for concern: regional and global impacts on ecosystems for different levels of climate change, Global Environmental Change 14, 219–228.

P.S. Any feasible planetary rescue strategy must include a method of removing some of the excess CO2 from the air.

I suggest the low cost, highly scalable, and technically feasible method of biosequestration.

I suggest engineering and extensively testing a GMO and seeding it into the ocean.

Hi Kris,

Steve McIntyre, a former mining executive, now a blogger and global warming denier, is blowing a small correction in our procedure of handling US data way out of proportion. The correction has absolutely no impact on the global mean temperature time series, over the US it made a difference of .15 C.

I checked what this correction does to your map and it does change the colors somewhat over parts of the US; the rest of the world is unaffected. Even the change over the US is way within the margin of error (0.5 C). So there is little need to make any changes.

The timing is a bit awkward, though. Sorry for that,

Reto

The current wind energy generating capacity in the U.S. could prevent the burning of 8.4 million tons of coal at the current utility fuel mix. For each megawatt of wind energy produced, 2,000 tons of carbon dioxide greenhouse gases are avoided, 10 tons of sulfur dioxide and 6 tons of nitrogen oxide. Power generated from coal and other fossil fuels, and the extraction of these fossil fuels have had, and will continue to have, impacts on birds. For example, more than 3,000 birds were killed by collisions during one night in fall migration at a four-smokestack Florida coal-fired power plant. Hundreds of thousands of birds were killed in the Exxon Valdez oil spill and thousands of acres of habitat were damaged.

ABC's Global Climate Change Program documents the significant changes in store for many migratory bird species in this century due to fossil fuel burning. Without a significant change in electrical power conservation and/or a major shift to alternative fuels, the U.S. is projected to increase its greenhouse carbon dioxide emissions between 2001 and 2025 by 43.5 percent. Global warming is predicted to cause changes in the ranges of birds, disruption of migration timing and synchrony with food resources. Avian species and some ecosystems may be threatened. For a state by state analyses of the effects on birds, go to ABC's web site at: <http://www.abcbirds.org/climatechange/statepage.htm> and access The Birdwatcher's Guide to Global Warming.

Jim, I fear you've overlooking significant available data on the issue of recoverable fossil fuels. The Energy Watch Group, a German NGO, has recently completed a study of global coal reserves and found that it's likely that reserves are far smaller than thought. See attached. Also, the EIA's projections of global oil supplies are simply not credible. Conventional oil production peaked in May, 2005, and it's likely we're at or very near a global peak of all liquids production today. See attached. So your estimates for fossil fuel use are likely far off the mark. This is good news of course, but doesn't moot the point that we are already on a path with current warming and current CO2 levels to warrant very aggressive action to mitigate climate change. At the least your paper should include discussion of these data. Hi Jim,

The more we learn it seems the more there are indications that we were doing harm to the balance way back. I interviewed Rajenda Pakuri yesterday chairman OF THE IPCC. He thinks we have about 2 1/2 degrees for certain in the pipeline so the questrion becomes what happened to your 1 degree to one in 1 1/2 warning in 2006? I willing to bet that we get 3 minimum to 5 maximum withing the next 30 years 455 to 535 ppm is a CERTAINTY.

Given the conservative nature of the IPCC I I was quite taken with his thoughts. Can we save it? We can give it a could but there are many condtradictions which he sees and is worrieed about those.

It will all depend on how soon the US takes action and what leverage we can put on China and the special interests meaning oil interests. With so much money in the ground the discussion of peak oil takes on new meaning. If we burn it all were done unless sequestered as you know. But what will the cost do to the economy?

This is the discussion that has to be highlighted! Have a good weekend and stay HEALTHY. An old farmer friend once said to me " you just can't help some people!"

Best,

To: James Hansen <jhansen@giss.nasa.gov>

<x-flowed>

Dear James Hansen,

Apparently, you have been criticized for using an atmospheric pulse response function of the Bern model in your recent manuscript on peak oil (Karecha and Hansen).

I would like to point out that using oceanic mixed layer and biospheric decay response functions as described in Joos et al., Tellus, 1996 would be a more appropriate choice. This would allow you to include the well understood non-linearities of aquatic carbonate chemistry, while still using a simple, transparent and cost-efficient approach. Please note that this old version of the Bern model used in the IPCC Second Assessment Record and for the determination of GWP in the Kyoto Protocol yields very similar results as the newer versions used in the TAR (Joos et al., GBC, 2001) and the AR4 (Plattner et al., J. Climate, 2007 submitted) and results are in the range of currently used carbon cycle models.

You can download a simple and tested fortran code from my home page
<http://www.climate.unibe.ch/~joos/prmodel>

The publications can also be downloaded as pdfs from my home page:
<http://www.climate.unibe.ch/~joos/publications>

From: Brandon Keim <brandon@earthlab.net>
Date: Fri, 10 Aug 2007 09:21:52 -0600
To: James Hansen <jhansen@giss.nasa.gov>

Jim,

Thank you. I put the response up

<http://blog.wired.com/wiredscience/2007/08/climate-expert.html>

and it was our most-read post of the day. The comments were predictable, but there was one that I wasn't sure about:

"Much of the perceived warming is artificial. NASA's dataset had an error in it. The error related only to U.S. temperature record, but it is still significant. NASA GISS corrected its temp record and now the current decade is cooler than the 1990s and the 1990s are cooler than the 1930s. This is a big story but has not been picked up by the media yet. Read this <http://data.giss.nasa.gov/gistemp/>"

If you've an extra couple minutes again for the blog -- is that argument you've come across before, and is it meaningful in any ways?

Thanks,

Brandon

On Aug 9, 2007, at 8:48 AM, James Hansen wrote:

No, you cannot blame individual events like that on climate change, as it was possible for them to occur even without the human-made changes to the atmosphere. However, it is fair to ask whether the human changes have altered the likelihood of such events. There the answer seems to be yes. Storms driven largely by latent heat, and that includes thunderstorms, are expected to become stronger as the air becomes warmer and contains more moisture. Global warming does cause just such a tendency. Jim

Dear Dr. Hansen,

I'm writing about yesterday's tornado for Wired's science blog, and have a quick question: did climate change cause it?

I know that's a very simplistic way of phrasing the question, but I figure that's how most people will be asking it.

If you have a couple minutes to jot down your thoughts, I'd love to see them and put them up on the blog.

Subject: Temperature data

From: @comcast.net>

Date: Mon, 20 Aug 2007 09:18:57 -0400

To: <James.E.Hansen@nasa.gov>, <makikosato@giss.nasa.gov>

Sorry to burden you with a quick question, which I hope one of you can answer. Our daily newspaper recently printed a column by Cal Thomas attempting to discredit concern about global warming by alleging that NASA was wrong in arguing that 9 out of 10 of the warmest years on record have occurred since 1995. Instead he says that thanks to McIntyre it is now clear that 4 of the 10 warmest years were in the 1930s, that 2000, 2002, 2003, 2004 actually fall behind 1900, and that the warmest year on record is 1934. I note that the GISS website does credit McIntyre with some kind of correction, but as I look at your latest graphs (perhaps I am not looking at the right ones) it does not appear to me that 1900 or the 1930s had record warm years. Since I hope to write an op-ed piece for the local paper (Naples Florida Daily News) I would like to know how much if any truth lies in what Thomas says. Thank you for any information you can provide, and again sorry to bother you.

Jim -

I think he's simply missing one of the main points of our paper, i.e. that one doesn't even need to factor in the unconventional fuels to realize that the conventional oil and gas reserves alone have enough carbon to get us to/above the dangerous CC threshold (assuming the fixed and conservative 2%/yr usage growth rate till "peak"). In defense of our approach though, we do incorporate some element of dynamism in our reserve estimates, by merely including the oil and gas reserve growth terms.

As for the fuel substitution issue raised by Smith and the attached paper, unless there continue to be extremely misguided fossil energy subsidy policies, it's hard to imagine that it will one day become practical to achieve that type of widespread substitution of unconventional for conventional fuels, simply because, forgetting the economic issues (which can be largely dealt with via a carbon price), the unconventional fuels are relatively inefficient *thermodynamically*. This is acknowledged in the attached paper, which while objecting to use of the term "peak", actually does a reasonably good job of outlining the potential problems of higher reliance on unconventional fuels.

Bottom line for me is that our approach is still sound since we already know what's likely to happen if we factor in the unconventional fuels....

Jim, As someone returning to the energy field after some years absence, I may be out of date myself, but I think some of the statements in this article skirt the edge of reality. Basically, the concept of "peak" oil is not a valid one from a climate or energy demand perspective, because it only refers to so-called "conventional oil" Even the term "conventional" is not fixed in time and space and thus not terribly useful in many circumstances -- look at deep off-shore production, now conventional but only becoming so a couple of decades back.

Even if we accept the term "conventional" to mean something fixed and

we accept that half of it has been pumped, which is quite doubtful, there is plenty more oil out there in enhanced recovery (EOR) and oil sands, even before going to synfuels. See Fig 1 in the attached paper which nicely shows this. Even if we somehow were to stop at oil sands, we would have probably have at least 4 times more oil available in the future from these sources (rest of conventional, EOR, tar sands). Given proven response to price in the past, one could argue for quite a bit more. With the estimates from synfuels, of course, the estimate become vast, with perhaps 20 times more to be sold than sold in the past. Add in oil shale, and it is larger still

The economic, environmental, water and other costs of doing these things (particularly oil shale), of course, are immense, but at \$100 bb/oil, they will likely be tapped barring restraints of other sorts. Also, of course, the GHG per unit oil delivered to the customer goes steadily up, not a good pattern.

A better term here is not "peak," which is misleading in the extreme, but "transition", i.e., to different geologic sources, efficiencies of conversion, environmental impacts, national distribution of resource holdings, etc.. This transition is already well underway with the high prices now prevalent. For example, production from Alberta oil sands (which has oil-equivalent resources exceeding those in Saudi Arabia I believe) now exceeds 1 million bb/d and is still growing. "Conventional" is changing yet again.

Hope this is useful./k

True....Although I suspect in this case it might be more of an issue of his not actually reading the damn paper closely enough, and not understanding our goals clearly enough. Also, the whole topic of energy futures is obviously a "delicate" one, and I suppose people can't be faulted for having their own (often long-held) biases which place them distinctly into one of two highly combative camps (optimists vs. pessimists).

Dear Dr Hansen

I was hoping you might be able to spare me a couple of minutes on the phone this morning (Monday) to help me with a story I am writing about NASA changing the rank of warmest years in the US. My name is Richard Luscombe and I'm a journalist working for The Scotsman, a national newspaper in the UK.

I would only require a couple of minutes of your time, just to try to get a better perspective of how the ranking change came about and its significance or otherwise to global warming trends. I have spoken to Stepehn McIntyre who sent GISS an email that apparently led to the change, and I would very much like to get your take on it before we go to press.

I apologise for the short-notice request but hope you could squeeze in a quick call to me at some point before my deadline of noon.

My telephone number (I'm based in Florida) is 954-755-5116.

Many thanks and best wishes

Richard

Hi Dr. Hansen, Was not able to find the document you sent on Implications of Peak Oil..." Also wondering if we'll be able to do that interview in the next month or so. My note to you was:

Any chance we could do something on a weekend day in the next 4 to 8 weeks? A lot of the young people in the video are now in college, so that would get more of them to the interview. If that's no good, give me a few weekday possibilities in September / October, and I'll work with that.<<

Hope to hear back soon. Would be happy to send you a review copy of the video as it is now, and best of luck with everything...

Subject: Resolving Skeptics vs. Hansen
From: FMims@aol.com
Date: Mon, 3 Sep 2007 13:08:36 EDT
To: jhansen@giss.nasa.gov
CC: @ieee.org

Dear Jim,

I've just submitted a letter to a leading journal that cites your soot vs. ice findings (after private review by a leading expert). The theme is that CO2 will be around for a century or more while the effect of anthropogenic soot can be reduced or even ended much more quickly. The purpose of the letter is that this is at least one area in which there is room for optimism.

Now I'm writing a newspaper column about the increasing web bandwidth devoted to questions about the USHCN, GHCN, and GISS wxr station sites, many of which clearly do not meet WMO standards. School GLOBE stations I've seen are better situated than some of the USHCN sites.

A few years ago when we both spoke at the Earth Explorers Institute at the Maryland Science Center, I was surprised to see a major, obvious problem with the NWS station adjacent to the museum. The station is surrounded by a high, black metal fence, and a large, black metal plate was lying on the ground directly under the sensor array, which I photographed. I contacted the NWS, and they agreed to remove the plate. They had no idea how long it had been in place.

A major criticism of GISS involves how the data from problem sites is corrected. There is widespread criticism that the GISS methodology is not published or understandable, and I want to put this criticism to rest in my column by giving your procedure for correcting a worse case site:

http://gallery.surfacestations.org/main.php?g2_itemId=1606

TUCSON 32.23°N, 110.95°W; 742 m
GISS Station ID: 425722740000

This site is over a small gravel pad in an asphalt street surrounded by large buildings. The explanation offered by a spokesman from U of AZ is that the site simulates desert conditions. However, back in 2004 I studied and published the ground temperature of gravel, asphalt and vegetation in a desert region of West Texas and found that asphalt and gravel are much hotter than the adjacent desert.

Thanks for your help with this.

Best regards,

Forrest

<x-flowed>

You need to start talking about the danger of methane hydrates. At least 75% of the hydrates that exist today were actually manufactured by the oil and gas industrie's practice of Enhanced Oil Recovery- EOR, whereby they use fresh water and liquid CO2 in the deep earth full of carbon to make it easier to get the oil and gas out of the ground. Methane hydrates are fragile; can not be harvested; have destroyed life on earth before when their quantities were much less and hold the power to create oblivion with today's quantities. They are not salt tolerant and have been exploding since 1947 shortly after off shore drilling began. They cause the dinoflaggia that were first discovered in 1947 and the excrement of the Dinoflaggia is lethal to flesh. (flesh eating). Scientists say that when we warm up between 3-5% more, it will produce a thermocline in our oceans that will cause mass disassociations of the hydrates. In the meantime, they cause extreme weather such as El Nino and La Nino during their diassociation periods, and they cause all rogue waves.

You are in a position that gives you the ear of the press; why do not you say something about this threat; surely you know about it.

CCNet 153/2007 - 17 September 2007 -- Audiatur et altera pars

ANOTHER PALEO-CLIMATE MYTH GOES UP IN SMOKE

New research fingers climate change, not humans, as the culprit for the extinction of Neanderthals on the Iberian Peninsula. The research contradicts prevailing theory which holds modern humans responsible for their demise. Writing in Quaternary Science Reviews, an international team of researchers used climate reconstructions based on marine records to determine that Neanderthal populations fluctuated due to climate change well before the first Homo sapiens arrived in the Iberian Peninsula.

--Mongabay.com, 30 April 2007

Here's some encouraging news for those of you out there who think we in the liberal media blame climate change on everything. A new study reports that catastrophic climate change did not - repeat not - kill the Neanderthals. The study, unfortunately, doesn't mention what did kill them off. Trans fats, perhaps?

--USA Today, 12 September 2007

Whatever it was that sealed the fate of the Neanderthals, it looks unlikely to have been climate change. That is the verdict of a new study that used climate records from Venezuela to deduce what happened at the Neanderthals' last stand at the southern tip of Europe. The research suggests that a switch to a cold, dry climate was probably not the telling factor in the demise of the Neanderthals, because of all the probable dates for their extinction, most do not lie near major cold events in the climate record.

--Michael Hopkin, Nature, 12 September 2007

The take-home message is that we can eliminate catastrophic climate change as a factor for Neanderthal extinction.

--Chronis Tzedakis, Nature, 12 September 2007

A claimed "first world conference on research integrity" opens in Lisbon, Portugal, today. The conference media release explains: "The controversies surrounding the recent assessment report of the United Nations' Intergovernmental Panel on Climate Change (IPCC) demonstrates how research integrity is a critical issue not only for the science community, but for politicians and the society as a whole as well. In August 2007 the US National Aeronautics and Space Administration (NASA) had to withdraw previous published historical climate data.

--Jennifer Marohasy, 16 September 2007

The development projects India is undertaking to reduce impacts of climate change is already cutting into its GDP. In 2006-07, India used 2.17% of its GDP on projects that will help communities adapt to climate change and reduce their vulnerability to climate change. This was disclosed on Thursday by Jayant M

Mau-skar, joint secretary in the environment ministry. Mauskar said, "In 2000-01, India was spending 0.63% of its GDP on climate change adaptation and mitigation which has now risen to 2.17%. So we can say that Nicholas Stern's argument (that climate change action does not hurt economy much) is perhaps not true."

(1) NEANDERTHALS 'NOT KILLED BY CLIMATE CHANGE'

Nature, 12 September 2007

<http://www.nature.com/news/2007/070910/full/070910-7.html>

Study suggests demise did not coincide with climate cooling.

Michael Hopkin

Whatever it was that sealed the fate of the Neanderthals, it looks unlikely to have been climate change. That is the verdict of a new study that used climate records from Venezuela to deduce what happened at the Neanderthals' last stand at the southern tip of Europe.

The research suggests that a switch to a cold, dry climate was probably not the telling factor in the demise of the Neanderthals, because of all the probable dates for their extinction, most do not lie near major cold events in the climate record.

Neanderthals (*Homo neanderthalensis*) lived in Europe until around 30,000 years ago

- not long after Homo sapiens arrived on the scene 40,000 years ago. The Neanderthals are thought to have lasted longest in the region around Gibraltar, off the southern tip of Spain.

"There are different factors that have been invoked to explain the Neanderthal extinction," says Chronis Tzedakis of the University of Leeds, UK, who led the new research. "Clearly the appearance of anatomically modern humans is the prime suspect, but given that the extinction happened during the last glacial period, when climate was changing, what we know is that the climate was extremely unstable at that time."

The main problem with testing the different theories comes from the difficulty in dating accurately the age of Neanderthal fossils and tools to compare their ages with records of past climate.

This is because 'radiocarbon dating' used on Neanderthal remains - in which researchers measure the amount of the radioactively decaying isotope carbon-14 in a sample to determine its age - is not directly related to calendar years. For very old samples, it can be used to tell whether one object is older than another, but not to determine their exact ages.

Like with like

Tzedakis and his colleagues got around this problem by comparing the radiocarbon dates of Neanderthal tools from Gorham's Cave in Gibraltar, with a very accurate set of radiocarbon dates of ocean sediments, in which the lives of tiny sea-creatures record the climate of the time. These well-dated sediments happen to come from Cariaco Basin, Venezuela.

The researchers report in Nature1, that of the three main radiocarbon dates given as possible extinction times for the Neanderthals - 32,000 years, 28,000 years and 24,000 years - only the most recent seems to have occurred at the same time as a climate shift. This most recent date is also the most controversial, meaning that it is generally more likely that it was competition with modern humans, rather than the bitter cold, that did for the Neanderthals.

"The take-home message is that we can eliminate catastrophic climate change as a factor for Neanderthal extinction," Tzedakis says.

The same method can be applied to assess the climatic conditions during any 'snapshot' event that is represented by accurately carbon-dated samples, Tzedakis adds. The climate in Venezuela is reflective of the climate in Europe, he adds, because many of Europe's climate shifts involved changes in the Gulf Stream, which influences climate from tropical America to the northern reaches of the Atlantic Ocean. And large climate swings, from warm and wet to cold and dry, tended to occur more or less all at once globally. "Changes from one condition to the other were extremely abrupt - of the order of a few decades," Tzedakis explains.

(2) CLIMATE DIDN'T KILL THE CAVEMEN

USA Today, 12 September 2007

<http://blogs.usatoday.com/weather/2007/09/climate-didnt-k.html>

Here's some encouraging news for those of you out there who think we in the liberal media blame climate change on everything. A new study reports that catastrophic climate change did not - repeat not - kill the Neanderthals.

These extinct archaic humans lived in parts of Europe and Asia for more than 100,000 years, before disappearing entirely some 33,000 to 24,000 years ago.

The causes of their extinction have puzzled scientists for years - with some believing it was due to competition with modern humans, while others blamed deteriorating climatic conditions.

But a new University of Leeds study -- using lots of sophisticated paleontological methodology that I don't begin to understand -- has shown that the Neanderthal extinction did not coincide with any of the extreme climate events that occurred during the last glacial period.

The study, unfortunately, doesn't mention what did kill them off. Trans fats, perhaps?

(3) POPULAR PALEO-CLIMATE MYTH: GLOBAL WARMING KILLED NEANDERTHALS

Mongabay.com, 30 April 2007

<http://news.mongabay.com/2007/0430-neanderthals.html>

New research fingers climate change, not humans, as the culprit for the extinction of Neanderthals on the Iberian Peninsula. The research contradicts prevailing theory which holds modern humans responsible for their demise.

Writing in *Quaternary Science Reviews*, an international team of researchers used climate reconstructions based on marine records to determine that Neanderthal populations fluctuated due to climate change well before the first *Homo sapiens* arrived in the Iberian Peninsula. They faced adverse weather conditions--including cold, arid and highly variable climate--at the time of their disappearance some 24,000 years ago, according to the researchers.

Dr. Clive Finlayson of the Gibraltar Museum led the research.

The Neanderthal (*Homo neanderthalensis*) was a species of the *Homo* genus that inhabited Europe and parts of western Asia as early as 350,000 years ago before disappearing some 33,000 to 24,000 years ago. Neanderthals had large braincases, short but robust and muscular builds, and large noses.

Research published in *Proceedings of the National Academy of Sciences (PNAS)* suggests that Neanderthals 43,000 years ago eked out a meager existence, possibly supplemented by cannibalism.

(4) MARS, LIKE EARTH, HAS CYCLICAL COLD AND WARM AGES, STUDY SAYS

National Geographic News, 14 September 2007

<http://news.nationalgeographic.com/news/2007/09/070913-mars-iceage.html>

Brian Handwerk

Mars has gone through 40 ice ages during the past five million years that regularly send the planet's permanent ice sheets cascading toward the equator, then melting backward, a new theory suggests.

The climate changes are likely driven by cyclical fluctuations in the planet's orbit that alter the amount of sunlight that falls on the planet's surface, says astronomer Norbert Schörghofer of the University of Hawaii at Manoa.

Understanding the sun's exact role in the Martian ice ages could help solve longstanding puzzles about the red planet.

It could also help scientists better understand Earth's complex climatic systems, which are also affected by orbital variations.

The new theory appears in this week's issue of the journal Nature.

Mystery of the Ice

In recent years extensive amounts of ice have been discovered below the surface of Mars. Much of the ice mysteriously survives far from the planet's poles.

Schörghofer suggests that this ice is newer than previously believed.

"Earlier theories have tried to explain this ice with snowfall that would have happened some five million years ago [but struggle] to explain how that ice could have stayed there," Schörghofer said.

"I'm saying it didn't stay. It went away and then came back many, many times."

According to Schörghofer, much of Mars's ice is formed by vapor diffusion—the seeping of gas directly into underground pockets during cold periods.

"The water cycle on Mars is very different than what we see on Earth," said Joshua Bandfield, a research specialist at Arizona State University's School of Earth and Space Exploration who was not involved in the study.

(5) MEDIA BS: MAMMOTH DUNG MAY SPEED GLOBAL WARMING

Reuters, 16 September 2007

http://today.reuters.com/news/articlenews.aspx?type=inDepthNews&storyid=2007-09-17T004817Z_01_L10768861_RTRUKOC_0_US-ARCTIC-RUSSIA-PERMAFROST-ENVIRONMENT-FEAT.xml&src=rss

By Dmitry Solovyov

DUVANNY YAR, Russia (Reuters) - Sergei Zimov bends down, picks up a handful of treacly mud and holds it up to his nose. It smells like a cow pat, but he knows better.

"It smells like mammoth dung," he says.

This is more than just another symptom of global warming.

For millennia, layers of animal waste and other organic matter left behind by the creatures that used to roam the Arctic tundra have been sealed inside the frozen permafrost. Now climate change is thawing the permafrost and lifting this prehistoric ooze from suspended animation.

But Zimov, a scientist who for almost 30 years has studied climate change in Russia's Arctic, believes that as this organic matter becomes exposed to the air it will accelerate global warming faster than even some of the most pessimistic forecasts.

"This will lead to a type of global warming which will be impossible to stop," he said.

When the organic matter left behind by mammoths and other wildlife is exposed to the air by the thawing permafrost, his theory runs, microbes that have been dormant for thousands of years spring back into action.

As a by-product they emit carbon dioxide and -- even more damaging in terms of its impact on the climate -- methane gas.

According to Zimov, the microbes are going to start emitting these gases in enormous quantities.

(6) INDIAN GOVERNMENT OFFICIAL REJECTS STERN REVIEW

The Times of India, 17 September 2007

<http://timesofindia.indiatimes.com/India>

[/Cost of dealing with climate change 2 of GDP /articleshow/2373069.cms](http://timesofindia.indiatimes.com/India/Cost_of_dealing_with_climate_change_2_of_GDP/articleshow/2373069.cms)

NEW DELHI: The development projects India is undertaking to reduce impacts of climate change is already cutting into its GDP. In 2006-07, India used 2.17% of its GDP on projects that will help communities adapt to climate change and reduce their vulnerability to climate change.

This was disclosed on Thursday by Jayant M Mau-skar, joint secretary in the environment ministry, at a conference on climate change organised at the Vatavaran Film Festival here. Mauskar said, "In 2000-01, India was spending 0.63% of its GDP on climate change adaptation and mitigation which has now risen to 2.17%. So we can say that Nicholas Stern's argument (that climate change action does not hurt economy much) is perhaps not true."

Stern, in his report on climate change for the UK, he had stated that taking action to reduce climate change would not hurt the growing economies of countries like India. The official, in a way, has showcased the argument that India could be taking to the negotiating table at the UN meeting on climate change when developed countries ask it to undertake cap on greenhouse gas emissions.

The pressure has been building on India and China to agree to some kind of emission cuts. The EU has been saying that it is the only way to convince the US and Australia to undertake commitments in the new phase of the Kyoto Protocol - something both countries stayed off saying it would hurt their economies without any real gain.

The ministry reached this figure by back calculating and claiming that several government programmes already address the key factors increasing vulnerability to climate change. The government has claimed that 22 programmes in crop management, 19 in drought proofing, 19 in health, six in risk finance, six in disease control, 12 in forestry and 30-odd in poverty alleviation fit the bill.

But some experts have contested these figures, proffered earlier in official meetings. While it is understood that India would use such a line of defence along with other more robust weapons in its armoury to defend any move to push it into commitments, experts have warned that such claims would not pass close scrutiny.

The next battle of sorts on the issue could come at the September 22 US-hosted meeting of major economies on energy security and climate change - what is informally called the meeting of the biggest polluters, the way US defines it - where India is also an invitee. At the last G8 meeting, the PM had laid down India's line that it would, despite its economic development, not exceed the per capita emissions beyond what the developed countries have or reach.

(7) TECHNOLOGICAL FIX: TAMING THE TSUNAMI RISK

New Scientist, 15 September 2007

http://technology.newscientist.com/article.ns?id=mg19526215.700&feedId=online-news_rss20

A "GPS shield" that works in real time could save lives by quickly warning of potential tsunamis.

The German-Indonesian Tsunami Early Warning System (GITEWS) is being developed by a team led by Jörn Lauterjung of the National Research Centre for Geosciences in Potsdam, Germany. Unlike a GPS method proposed last year, which detects seismic waves transmitted through the Earth's crust to distant receivers, the new ground-based system takes real-time measurements of vertical ground motion - the type of fault movement more likely to produce tsunamis (Journal of Geophysical Research, DOI: 10.1029/2006JB004640).

To protect the Indian Ocean region, the proposed shield would include an array of 18 GPS stations.

(8) CONFERENCE ON INTEGRITY IN SCIENCE FOCUSES ON IPCC

Jennifer Marohasy, 16 September 2007

<http://www.jennifermarohasy.com/blog/archives/002299.html>

A claimed "first world conference on research integrity" opens in Lisbon, Portugal, today. The conference media release explains: "The controversies surrounding the recent assessment report of the United Nations' Intergovernmental Panel on Climate Change (IPCC) demonstrates how research integrity is a critical issue not only for the science community, but for politicians and the society as a whole as well. In August 2007 the US National Aeronautics and Space Administration (NASA) had to withdraw previous published historical climate data.

The incident came after a British mathematician discovered that the sources used by the Intergovernmental Panel for Climate Change (IPCC) have disregarded the positions of weather stations, plus intentionally using outdated data on China from 1991 and ignoring revised data on the country from 1997.

Now 350 concerned scientists, scientific managers and magazine editors from around the world are scheduled to attend the event in Lisbon, initiated and organised by the European Science Foundation (ESF) and the US Office for Research Integrity (ORI). It marks a milestone for the science community as it will link all those concerned parties in a global effort to tackle the issue head on.

"At the very least, countries should know how misconduct will be handled in other countries and whom to contact if they have questions. A more ambitious goal is to begin to harmonize global policies relating to research integrity," says Conference Co-Chair Nicholas Steneck from the University of Michigan.

"By now there are no consistent global standards for defining and responding to major misconduct in research. Definitions and practices vary from country to country and even institution to institution. Improper practices that could be ignored in one country could get a researcher dismissed from a position in another country," Steneck adds.

The conference will be focusing on both individual and institutions' responsibilities, and of funding agencies as well as publishers, according to Conference Co-Chair Tony Mayer from the Nanyang Technological University in Singapore. Mayer is also the former Senior Science Policy Adviser to the ESF.

Jose-Mariano Gago, the Portuguese Minister of Science, Technology and Higher

Education, Janez Potocnik, the European Commissioner for Research, Angel Gurriza, the Secretary-General, Organisation for Economic Co-operation and Development (OECD), and Tim Hunt from the Cancer Research UK, South Mimms will kick off the event by participating in the opening talks. .

In his keynote address, Paul David from the Oxford University, UK, and Stanford University, Palo Alto, U.S., will give an overview on analytical and empirical studies of ORI on the problem of scientific misconduct. David is well known for his research in the economics of science and technology, with special reference to the impact of intellectual property rights protections on the direction and conduct of 'open science' research.

Howard Alper, Professor of Chemistry and Vice-President Research at the University of Ottawa, and winner of the first Gerhard Herzberg Canada Gold Medal in Science and Engineering, Canada's most prestigious award for science and engineering, is also affiliated with the International Development Research Centre (IDRC), Canada, because he is also an expert in the situations in developing and emerging countries. From his experiences he presents the best practices for the benefit of a society.

Herbert Gottweis from the Institute of Political Sciences, University of Vienna, Austria, will reconsider the Hwang gate from 2005 and present the lessons learned. Gottweis is vice-president of the Austrian Research Fund (FWF) and coordinator of the PAGANINI ("Participatory Governance and Institutional Innovation") project of the European Union.

The conference will also touch on the situation in developing and emerging countries, where scientists often have to produce publications in numbers under pressure to achieve the formal scientific qualifications. Thus voices from Africa, like that from Amaboo Dhai, University of the Witwatersrand Medical School, Steve Biko Centre for Bioethics, Parktown, South Africa, will also be heard. In addition, Annette Flanagin of JAMA, the Journal of the American Medical Association, and Muza Gondwe, University of Malawi, College of Medicine, Blantyre, will contribute their experiences from the "African Journal Partnership Project". Flanagin is the author of the JAMA Manual of Style: A Guide for Authors and Editors, now in it's 10th edition.

In other words the World Conference on Research Integrity focuses on an open sore of science, taking into consideration the reality, legal and institutional aspects, as well as regional, social and psychological environments in which scientists work. It intends to be the beginning of the healing process.

For more information on the conference please go to:
<http://www.esf.org/conferences/researchintegrity>

Live news and photos from the event will be posted on the ESF Media Centre:
<http://www.esf.org/media-centre.html>

(9) RUSSIAN SCIENTISTS MULL ANTI-ASTEROID SYSTEM

Itar-Tass, 17 September 2007
<http://www.itar-tass.com/eng/level2.html?NewsID=11876528&PageNum=0>

MOSCOW, September 17 (Itar-Tass) - On the day of the 150th anniversary of the birth of Eduard Tsiolkovsky, the founder of world cosmonautics, scientists meet in Kaluga to discuss matters aimed at protecting the Earth from asteroids.

Alexander Vorobyov, press secretary of the Roscosmos (Russia's Federal Space Agency) has told Itar-Tass that this problem will be one of central subjects of discussion at the 42nd scientific readings on prospects for the development of cosmonautics. The Readings begin in Kaluga, the birth town of the great scientist, on Monday.

The importance of the problem of creating a system for the protection of the Earth from asteroids is connected with the fact that, according to estimates by specialists, Asteroid Apophis will fly by the Earth at a distance of less than 40,000 km in the year 2029, and that there is a high (sic!) probability of the asteroid's collision with the Earth in 2036.

Copyright 2007, ITAR-TASS

EDITOR'S NOTE: The impact probability is actually minute and is almost certainly going to become zero with additional observations. BJP

(10) GLOBAL WARMING CAUSES NASA MELTDOWN?

Oliver Manuel [omatumr@yahoo.com]

Hi Benny,

Steve McIntyre at Climate Audit seems to be witnessing a meltdown at NASA as he continues to find evidence of changes in the experimental temperature database which Dr. James E. Hansen used as evidence for global warming.

<http://www.climateaudit.org/?p=2049> - more-2049

I suspect that NASA has used some of the same tricks to peddle AGW (anthropologic global warming) that it used to promote the myth that planet Earth is heated by a steady, H-fusion reactor in the core of a Hydrogen-filled Sun.

Since the 1969 Apollo Mission returned the first lunar soils loaded with solar-wind-implanted material, NASA has successfully manipulated the press and access to funds, samples, and Lunar Science Conferences to hide experimental evidence that planet Earth is heated by a neutron star at the core of an iron-rich Sun - the remains of an object that exploded five (5) billion years ago and ejected the material that now orbits it.

With kind regards,

Oliver K. Manuel

Emeritus Professor, Nuclear Chemistry

Hi Leslie,

I saw this story in the Toronto Star today (<http://www5.lexisnexis.com/publisher/EndUser?Action=UserDisplayFullDocument&orgId=101937&topicId=10603004&docId=1:655133574>) and wanted to check its veracity.

I hadn't heard about a revision to NASA's temp readings that would make 1934 the hottest on record (rather than 1996). If there has been a revision, please point me in the right direction, so I can understand the new results and what changed.

Thanks,
Dan

Jim, As someone returning to the energy field after some years absence, I may be out of date myself, but I think some of the statements in this article skirt the edge of reality. Basically, the concept of "peak" oil is not a valid one from a climate or energy demand perspective, because it only refers to so-called "conventional oil" Even the term "conventional" is not fixed in time and space and thus not terribly useful in many circumstances -- look at deep off-shore production, now conventional but only becoming so a couple of decades back. Even if we accept the term "conventional" to mean something fixed and we accept that half of it has been pumped, which is quite doubtful, there is plenty more oil out there in enhanced recovery (EOR) and oil sands, even before going to synfuels. See Fig 1 in the attached paper which nicely shows this. Even if we somehow were to stop at oil sands, we would have probably have at least 4 times more oil available in the future from these sources (rest of conventional, EOR, tar sands). Given proven response to price in the past, one could argue for quite a bit more. With the estimates from synfuels, of course, the estimate become vast, with perhaps 20 times more to be sold than sold in the past. Add in oil shale, and it is larger still The economic, environmental, water and other costs of doing these things (particularly oil shale), of course, are immense, but at \$100 bb/oil, they will likely be tapped barring restraints of other sorts. Also, of course, the GHG per unit oil delivered to the customer goes steadily up, not a good pattern. A better term here is not "peak," which is misleading in the extreme, but "transition", i.e., to different geologic sources, efficiencies of conversion, environmental impacts, national distribution of resource holdings, etc.. This transition is already well underway with the high prices now prevalent. For example, production from Alberta oil sands (which has oil-equivalent resources exceeding those in Saudi Arabia I believe) now exceeds 1 million bbl/d and is still growing. "Conventional" is changing yet again. Hope this is useful./k p.s. I copy who may have some corrections or elaborations. At 06:27 PM 9/7/2007, you wrote: >To be removed from Jim Hansen's e-mail distribution respond with >REMOVE as subject > >http://www.columbia.edu/~jeh1/distro_peakrevandgistemp_070907.pdf > Attachment Converted: "c:\program files\qualcomm\eudora\attach\Farrell and Brandt.pdf"

Subject: Regarding the criticisms of McIntyre et al
From: @sbsoft.com>
Date: Mon, 17 Sep 2007 20:10:16 -0400
To: <James.E.Hansen@nasa.gov>
CC: @sbsoft.com>

Dear Sir:

I don't understand your recent approach in dealing with the recent criticisms of Steve McIntyre and friends.

As you recently noted (and McIntyre agrees), none of these criticisms have a material effect on global temperature.

The credibility of GISS (and other organizations aggregating temperature data) DOES have a material impact on any analysis of global temperature.

If McIntyre shows that you have an agenda, then your data (and the conclusions supported by your data) are weakened.

By making undocumented changes to your methodology (which McIntyre subsequently dissects on his blog) you provide ammunition to those who insist that you have agenda, and that your agenda is tainting your data.

Why not adopt an ultraconservative approach in all of the changes that you make? Why not:

1. avoid making changes except in the case of outright errors
2. publicly document all changes at the time they occur
3. graciously thank McIntyre et al for any errors they bring to your attention
4. avoid making editorial statements, and let the data speak for itself.

It makes no difference whether 1934 or 1998 was warmer in the United States. But your recent statements and changes have created the impression that GISS cares about this issue, and is willing to change its methodology accordingly.

It makes little difference whether or not this is true. What matters is whether or not you have created a trail of data that would allow an observer to reach the conclusion that your agenda has impacted your actions.

I think you have, and that this is infinitely more damaging than a temperature adjustment here or there.

Sincerely,

Dr. James Hansen, Director
NASA Goddard Institute for Space Studies
2880 Broadway
New York, N.Y. 10025

Dear Dr. Hansen,

I just read *Peak Oil and Global Temperature* on your website. How close do you think we are to reaching a 'dangerous' level of atmospheric carbon dioxide? Extrapolation of the 1958-2005 CO₂ curve, which assumes business as usual, indicates a concentration of 490 ppm in 2050, which must far exceed a dangerous level. It will reach 450 ppm in one generation, by 2037. How will we know when a truly hazardous level for life has been reached? In many respects, e.g. greatly diminished Arctic sea ice cover, it seems we may have already passed a point of no return.

I may have stumbled upon a signal that indicates a critical threshold in the global climate was reached about 1990, introduced in a 2003 paper published in *Polar Geography* (reprint enclosed). Also see: http://www.hymet.com/docs/POLAR%2027n04_320-338-Tangborn.pdf

In the study, daily temperature departures for 74 weather stations in the US, Europe, Asia and Australia were determined for the 1951-1999 period, based on 1932-1950 daily averages. In the 1980s an unusual seasonal pattern in these departures began to appear: for a few days each winter up to 90% of the stations were synchronized (had positive departures on the same day). The share reached 95% in 1990 and exceeded 90% 100 times throughout the 1990s. Although it is barely mentioned in the paper, I now feel certain that this phenomenon is caused by CO₂ reaching a critical concentration level (it was 350 ppm in 1990).

As CO₂ concentrations rise, wouldn't you expect the atmosphere to respond by gradually allowing the effect of greater trapped radiation to dominate temperature forcing for short periods in scattered areas? Then, as the concentration increases, its influence would tend to last a few days longer each year and affect more and more temperature observation stations throughout the world.

But to verify and better understand these findings, the study needs to be repeated and expanded by increasing the number of global stations and updating the period of record through at least 2006. If you know of anyone willing to take this on, I would be pleased to work with him (or her), and start by providing about 100 files of 1932-2006 US temperature data and the Fortran programs written for the project.

Sincerely,

Wendell Tangborn

Good Morning Mr. Hansen,

Today's Wall Street Journal has an article on page A14 titled, Not So Hot. Stephen McIntyre found that NASA made a technical error in standardizing the weather air temperature data post 2000. Curiously and most interesting is that these temperature mistakes were only for the United States; their net effect was to lower the average temperature reading from 2000-2006 by 0.15C.

It is interesting that Mr. Hansen has been unapologetic about NASA's error. I don't see the point of getting excited about global warming, if NASA's chief is going to ignore its error and continue about the global warming issue, when this article explicitly shows that 1934 was the warmest year on record. Ignoring facts is not very scientific; I hope that Mr. Hansen does not call himself a scientist, since he chooses to ignore truth along with Al Gore.

Subject: Mean Global Temperature - not anomaly

From: @ com>

Date: Mon, 6 Aug 2007 02:43:24 -0400

To: James.E.Hansen@nasa.gov

Hello Dr. Hansen,

Recently I have been researching various online resources for climate and temperature data. I ran across your name as an authority on the matter, and was wondering if you could be of assistance. My goal is to write a piece of software that both visualizes and sonifies the average global temperature for the past 100-200 years. I have found some excellent data on this site: <http://data.giss.nasa.gov/gistemp/> however this data seems to only list anomalies whereas I am interested in the mean data.

The project that i am working on is for a college art project - my use of the data relates to the cultural significance of this data - not explicitly the scientific significance. Is this data available in a format that lists the average (not anomaly) global temp (land, oceanic, or both) since 1880? If so, is it broken down into monthly averages?

I would be very appreciative if you could provide this information or point me in the right direction. I'd be happy to send you a CD or DVD of the composition when completed.

Please let me know.

Best,

'Hottest Year' Data Meltdown

By Tobin Harshaw

Tags: global warming

You just thought you were sweating? Among global warming Cassandras, the fact that 1998 was the "hottest year on record" has always been an article of faith. Stephen McIntyre, who runs the Climateaudit blog was always puzzled by some gaps he saw in the raw data provided by NASA that supported the claim (data compiled in part by James Hansen, the climate scientist who has long accused the Bush administration of trying to "silence" him). McIntyre says he has "reverse engineered" the data to find NASA's algorithm, discovered that a Y2K bug played havoc with some of the numbers, and notified the space agency.

Michael Asher at DailyTech explains the fallout:

NASA has now silently released corrected figures, and the changes are truly astounding. The warmest year on record is now 1934. 1998 (long trumpeted by the media as recordbreaking) moves to second place. 1921 takes third. In fact, 5 of the 10 warmest years on record now all occur before World War II. Anthony Watts has put the new data in chart form, along with a more detailed summary of the events.

The effect of the correction on *global* temperatures is minor (some 1-2% less warming than originally thought), but the effect on the U.S. global warming propaganda machine could be huge.

Note: Many commenters on this post have assumed that the author intended the term "Cassandras" to be pejorative, and also that he was unaware that the predictions made by the prophetess Cassandra, daughter of King Priam of Troy, came true. Rather, the term was being used in its common modern sense: one whose dire predictions, true or false, go unheeded.

Is this the New York Times or Fox News? The "U.S. global warming propaganda machine"? Are you kidding? The trend is toward warming, regardless of which are the peak years. How ironic that a propaganda piece complains about propaganda.

Dear Sir

In much the same way shouting "fire" in a crowded room is illegal, I believe people who can look directly at the polar ice caps melting and deny it should be incarcerated. This is a time for serious minded people to work together to solve the problems ignored by our war loving, SUV driving, coal burning friends from the right. KFH

That corrected NASA data is for the lower 48 states, not the globe.

It is well established that the greatest effect of global warming is being seen in polar regions, which are not covered by this report.

kevin hunter—What's to solve? Warmer temperatures means longer growing seasons and less need for fossil fuel for winter heating. Sure there'll be major issues to tackle but most are technologically solvable. The major banks and the General Electrics would be happy to finance such projects.

As I look at the 5 year mean anomaly data in the second column, the recent years remain the highest using the rolling averages. Probably a better measure than any single year.

The agenda of Harshaw and Asher, ignoring 5 year average temperature data, polar ice cap melting and rising CO2 — clearly suspect.

I'm a skeptic, but I still want cleaner air, lower carbon emissions and less oil dependency. I'm a skeptic because I still find it hard to believe that a century worth of data can give us clues about trends on a planet with billions of years of history. At the same time, I'm adamant about environmental issues because the benefits go beyond global warming. The benefits of increased health, cleaner air and not having to invade countries to

protect our oil supplies makes me want to buy a Prius. Also, if my skepticism is ill founded and global warming is due to human activity, we will accomplish all the goals with the same effort.

Paul—polemics and spin aside, this article points out a data correction. You may not like it as it doesn't support your point. Neither does it invalidate it. But it seems to me to be good faith data.

Kevin—The article I read does not speak of polar ice caps. It simply corrects a seemingly flawed piece of information. I think suggesting jail time is an exuberant reaction to a straw man of your creation that did not exist in the article I read.

Jim—Your point seems reasonable.

"Among global warming Cassandras" ... ?

Let's review the facts so far.

1. Stephen McIntyre is a former mining industry executive.
2. Until 2003, he was employed by CGX Energy Inc as a strategic advisor, with the specific task of disproving the validity of global warming.
3. The sole purpose of his website's existence is to disprove global warming, and he retains a direct financial stake in pushing the theory that global warming is a myth.
4. Now Mr. McIntyre has claimed that, due to computer errors supposedly caused by the Y2K bug, NASA should use HIS figures in place of blank areas which NASA did not have data for...
5. NASA, operating under the direction of the Bush Administration- which is beholden to exactly the same companies to which Mr. McIntyre is beholden- quietly and without debate adopts his figures...
6. ...and suddenly the biggest piece of data proving the existence of global warming disappears.

Mr. Harshaw, I don't know if you are aware of this, but Cassandra got her reputation by always being RIGHT- but no one ever believed her until it was too late.

And you, sir, are being played for a fool.

I think you should also look at the 5-year mean (third column of that NASA dataset). This clearly shows that the highest value was in 2000, with several other highs in the last decade. The five-year mean is a better indicator of temperature trends than the value in any one year, which may well reflect the influence of a single extreme weather event more than general trends in climate.

Not to mention that the "warmest years" statistic almost entirely useless, except as a shorthand for sensationalists, (of all stripes, it seems). The rest of us (tho perhaps few media outlets) recognize that the "warmest years", being outliers, are the least accurate index of central tendency, and shrug at this re-shuffling of the "Top 10". A simple linear graphing of the new NASA data still shows notable warming across the past three decades.

These kinds of pop media posts on serious scientific issues are I believe a major contributor to the criminal politicization of science. No less than the New York Times, by allowing such unconsidered posts, enables the trivialization of a solid and growing body of evidence supporting the global warming hypothesis (NOT PROPAGANDA), culled by hundreds of scientists worldwide. This hypothesis is not dependent on the single datum of "warmest year on record" but by thousands of other credible measurements, peer-reviewed and vetted, that are apparently invisible and may be incomprehensible to The Opinionators. I suggest the New York Times keep their bloggers away from such serious topics until they've learned how science works.

1:56 pm

Amen to the three above comments. To polarize this into a political issue and to belittle "global warming Cassandras" is to simply choose destruction over survival by never addressing the problem and blaming pea-brained fellow humans, all of whom are sunk and sinking unless we dramatically and quickly come up with non-COs emitting alternatives...Already hardly likely, but we should at least die fighting...We are indeed at a climate crisis, not because of what surface temperatures have or have not done before and after WWII, but because we currently have the highest human population EVER in the history of the earth, and the bulk of it is attempting to industrialize with completely unsustainable methods. The total of 500 million cars worldwide is unprecedented, and has almost doubled since 1998 alone—if it doubled in a mere 20 years, what is to happen in the next 20?

When I first learned to drive at age 16 in 1984, the majority of cars in the D.C. area not only obeyed traffic laws, but went below the speed limit, and people were actually ticketed for going 57 or 58. Now the trend towards utter lack of enforcement has led to absolutely lawlessness and flagrant disregard for all speed limits on every major highway and road, to the point that everyone feels they have to be aggressive in return just to survive. This trend is a huge failure of public policy....Similarly, we are accelerating our consumption of energy because of the complete lack of punishment or incentive for alternatives by either government, corporations, or bands of good citizens.

For the New York Times (my beloved Times, even though I am a lifelong native Washingtonian) to print such a foolishly polarizing statement, to insist that global warming is a political, not a survival issue, really wounds me. But perhaps a Fox fa**ist really did infiltrate the paper via some nasty web bug. Hallelujah that the Times provides such a revered and public forum so that Andrew Revkin is heard.

But ultimately I remain deeply pessimistic that so much damage has been done...Not merely population, but energy consumption, is so staggering it is beyond the capacity of any single pea-brained human to comprehend, let alone to change as quickly as we need to. I hug my young daughter as tightly as I can every day, I relish Chekhov and Turgenev as some of the only wisdom and consolation to the hopelessly ineffectual political and corporate and citizen avenues of change. We all just have one extremely short life, and it may quickly become much shorter for future generations. Enjoy blaming leftists or rightists or calling people alarmist as we all choke on polluted air and sink aboard the Titanic, if that is how you feel you need to live your short, brutish life. I would rather not only work to a real solution, but accomplish it.

Re: response of Mark Klein, M.D.

Dear Dr. Klein,

See number five, below:

The sort of leaders we need now are not those who promise ultimate victory over Nature through perseverance in living as we do right now, but those with the courage and intelligence to present the world what appears to be Nature's stern but reasonable surrender terms:

1. Reduce and stabilize your population.

2. Stop poisoning the air, the water, and the topsoil.
3. Stop preparing for war and start dealing with your real problems.
4. Teach your kids, and yourselves, too, while you're at it, how to inhabit a small planet without helping to kill it.
5. Stop thinking science can fix anything if you give it a trillion dollars.
6. Stop thinking your grandchildren will be OK no matter how wasteful or destructive you may be, since they can go to a nice new planet on a spaceship. That is really mean and stupid.
7. And so on. Or else.

The conclusions are not supported by the data—the data is ANOMALIES, that is deviations from the period average, not the absolute temperature. Thus if the period average for 1934 (30 yr) is colder, a lower 1934 temperature will produce a higher anomaly. In fact, the global temperature index on the same site shows that the average around 1934 was much lower than the average around 1998: the conclusion is that 1998 was hotter.

In fact, if the factors producing random variation in temperature have not changed much, the anomalies should be evenly distributed over time, regardless of the trend.

NASA's corrected data shows that the last 9 years are consistently warmer than normal. There is no other non-overlapping 9-year period in the entire database since 1880 that is as warm as the most recent 9-yr period. If there is global warming it would be identified from a persistent warming over a long period. Nine years may not be long enough, to justify a definitive conclusion but a pattern such as this cannot be ignored. The fact that 1934 was warmer than 1998 is not valid support for denial of the onset of detectable global warming.

Dr. Klein: your argument about "technological fixes" would be easier to accept if the earth were not (unfortunately in context) a sphere. Yes, as the Earth warms, land may become arable further north, and substantial natural resources may become open to exploration.

The cold regions that will become warmer are relatively small. The hot ones that will become hotter are huge. When large sections of South America, Africa, and Asia become too hot to live in — and vast populations of impoverished refugees start migrating north and south into more developed countries — what "technological fixes" do you propose?

As I understand it, the argument for manmade global warming points out a cluster of recent years which are all among the warmest on record, not just a single blip in the data due to normal fluctuations as in 1934. The point is, if decreasing the manmade component in warming can reduce the overall severity of the warming and its negative consequences, we should do it. And as one reader pointed out, there are many other positive reasons to do so, such as decreasing our dependence on oil, which we need to do anyway before it runs out.

Climate change science is not (as skeptics seem to believe) like a "house of cards", ready to tumble down through a singular study or "data meltdown." Rather, climate change science is like a complex puzzle, many of the pieces having been firmly in place for over 100 years, becoming further resolved and assembled in the gradual process that is science. The pace of assembly has quickened substantially in recent decades to the point that the puzzle's essential landscape and image are clear. At most, a new study (or "data meltdown") may require that a piece or two need to be modified in shape or tint, but the basic picture being assembled remains firmly in place. It seems that the climate change "alarmists" are not the scientists who methodically spell out for us a very sobering picture of our future, lest we change, but those who think this well-grounded understanding of real processes may be overthrown through a singular and sudden bit of news. I wish it were so, but wishful thinking is not a solution in this case.

I don't get the spin on this one, it looks like a good example of scientific progress at work. one group points out an error in another group's work. the other group updates their method to account for it, and publishes the data. the essential hypothesis is still supported by the data—the trend is obviously significant for the US and the world, so what's the story here?

also, if you had any idea of what happened in 1934 (think dust bowl...), and the indication is that is the direction we are headed, maybe you wouldn't be so quick to jump on this one.

'Hottest Year' Data Meltdown

By Tobin Harshaw

Tags: global warming

You just thought you were sweating? Among global warming Cassandras, the fact that 1998 was the "hottest year on record" has always been an article of faith. Stephen McIntyre, who runs the Climateaudit blog was always puzzled by some gaps he saw in the raw data provided by NASA that supported the claim (data compiled in part by James Hansen, the climate scientist who has long accused the Bush administration of trying to "silence" him). McIntyre says he has "reverse engineered" the data to find NASA's algorithm, discovered that a Y2K bug played havoc with some of the numbers, and notified the space agency.

Michael Asher at DailyTech explains the fallout:

NASA has now silently released corrected figures, and the changes are truly astounding. The warmest year on record is now 1934. 1998 (long trumpeted by the media as recordbreaking) moves to second place. 1921 takes third. In fact, 5 of the 10 warmest years on record now **all occur before World War II**. Anthony Watts has put the new data in chart form, along with a more detailed summary of the events.

The effect of the correction on *global* temperatures is minor (some 1-2% less warming than originally thought), but the effect on the U.S. global warming propaganda machine could be huge.

Note: Many commenters on this post have assumed that the author intended the term "Cassandras" to be pejorative, and also that he was unaware that the predictions made by the prophetess Cassandra, daughter of King Priam of Troy, came true. Rather, the term was being used in its common modern sense: one whose dire predictions, true or false, go unheeded.

Is this the New York Times or Fox News? The "U.S. global warming propaganda machine"? Are you kidding? The trend is toward warming, regardless of which are the peak years. How ironic that a propaganda piece complains about propaganda.

Dear Sir

In much the same way shouting "fire" in a crowded room is illegal, I believe people who can look directly at the polar ice caps melting and deny it should be incarcerated. This is a time for serious minded people to work together to solve the problems ignored by our war loving, SUV driving, coal burning friends from the right. KFH

That corrected NASA data is for the lower 48 states, not the globe.

It is well established that the greatest effect of global warming is being seen in polar regions, which are not covered by this report.

kevin hunter—What's to solve? Warmer temperatures means longer growing seasons and less need for fossil fuel for winter heating. Sure there'll be major issues to tackle but most are technologically solvable. The major banks and the General Electrics would be happy to finance such projects.

As I look at the 5 year mean anomaly data in the second column, the recent years remain the highest using the rolling averages. Probably a better measure than any single year.

The agenda of Harshaw and Asher, ignoring 5 year average temperature data, polar ice cap melting and rising CO2 — clearly suspect.

I'm a skeptic, but I still want cleaner air, lower carbon emissions and less oil dependency. I'm a skeptic because I still find it hard to believe that a century worth of data can give us clues about trends on a planet with billions of years of history. At the same time, I'm adamant about environmental issues because the benefits go beyond global warming. The benefits of increased health, cleaner air and not having to invade countries to protect our oil supplies makes me want to buy a Prius. Also, if my skepticism is ill founded and global warming is due to human activity, we will accomplish all the goals with the same effort.

Paul—polemics and spin aside, this article points out a data correction. You may not like it as it doesn't support your point. Neither does it invalidate it. But it seems to me to be good faith data.

Kevin—The article I read does not speak of polar ice caps. It simply corrects a seemingly flawed piece of information. I think suggesting jail time is an exuberant reaction to a straw man of your creation that did not exist in the article I read.

Jim—Your point seems reasonable.

"Among global warming Cassandras"...?

Let's review the facts so far.

1. Stephen McIntyre is a former mining industry executive.
2. Until 2003, he was employed by CGX Energy Inc as a strategic advisor, with the specific task of disproving the validity of global warming.
3. The sole purpose of his website's existence is to disprove global warming, and he retains a direct financial stake in pushing the theory that global warming is a myth.
4. Now Mr. McIntyre has claimed that, due to computer errors supposedly caused by the Y2K bug, NASA should use HIS figures in place of blank areas which NASA did not have data for...
5. NASA, operating under the direction of the Bush Administration- which is beholden to exactly the same companies to which Mr. McIntyre is beholden- quietly and without debate adopts his figures...
6. ...and suddenly the biggest piece of data proving the existence of global warming disappears.

Mr. Harshaw, I don't know if you are aware of this, but Cassandra got her reputation by always being RIGHT- but no one ever believed her until it was too late.

And you, sir, are being played for a fool.

I think you should also look at the 5-year mean (third column of that NASA dataset). This clearly shows that the highest value was in 2000, with several other highs in the last decade. The five-year mean is a better indicator of temperature trends than the value in any one year, which may well reflect the influence of a single extreme weather event more than general trends in climate.

Re: MARK KLEIN's comment: "Sure there'll be major issues to tackle but most are technologically solvable." This might be the case for some areas of human activity, but is not true for many non-human species that cannot adapt and face extinction. Life is an interconnected web. If we create the conditions that drive many species to extinction, we will be living on a different planet.

Not to mention that the "warmest years" statistic almost entirely useless, except as a shorthand for sensationalists, (of all stripes, it seems). The rest of us (tho perhaps few media outlets) recognize that the "warmest years", being outliers, are the least accurate index of central tendency, and shrug at this re-shuffling of the "Top 10". A simple linear graphing of the new NASA data still shows notable warming across the past three decades.

These kinds of pop media posts on serious scientific issues are I believe a major contributor to the criminal politicization of science. No less than the New York Times, by allowing such unconsidered posts, enables the trivialization of a solid and growing body of evidence supporting the global warming hypothesis (NOT PROPAGANDA), culled by hundreds of scientists worldwide. This hypothesis is not dependent on the single datum of "warmest year on record" but by thousands of other credible measurements, peer-reviewed and vetted, that are apparently invisible and may be incomprehensible to The Opinionators. I suggest the New York Times keep their bloggers away from such serious topics until they've learned how science works.

The data that you link to—temperature data for the lower 48 states since 1880—show an average rate of warming of 0.5 degrees C per century over that period, and that the rate of warming is accelerating. This is supposed to discredit "global warming Cassandras"? Who cares whether 1934 was 0.02 degrees hotter (in the lower 48 states) than 1998?

I guess the suggestion is that the "U.S. global warming propaganda machine" was going around saying that 1998 was the hottest year on record in the lower 48 states, and that this data shows that they are liars. But can you find any reference of someone spouting about 1998 being the hottest year on record in the lower 48 states? If anything, you will see claims that 1998 was the hottest year on record, period—and 1998 was (at the time) the hottest year on record, if you look at the global data, which is obviously more relevant to the issue of "global" warming than data for the lower 48 states. (Of course, 1998 has since been supplanted by 2005 as the hottest year on record.)

It's regrettable that people on either side draw attention to tiny pieces of data (such as the temperature in any one year), when it is the long-term trends that are of true significance. But if you're going to attack someone on the basis that they don't have their facts straight, then please attack an actual individual or organization instead of a straw man.

August 10th,
2007
1:50 pm

The term "hottest year on record" isn't appropriate unless you're talking about global climate. But you're only talking about the lower 48 states. Why would you use such misleading language if you're trying to educate people? By the same token, why use terms like "U.S. global warming propaganda machine" and use scare quote around the word "silence." Hansen claimed that NASA tried to silence him, not "silence" him.

If you want to discuss facts, there's plenty to discuss. If you want to use inflammatory and misleading language that is certainly your prerogative, but aren't there more appropriate places to do that than the New York Times?

NB: Cassandra was right, remember? Her curse was to accurately predict the future but not to be believed. So calling someone a Cassandra is to imply that they are correct but unpopular.

Global Warming... just another excuse for activists to go around blaming humankind for something that occurs naturally. In 10 years Global Warming will be in the same category as the gas crisis (of the 70's), the world population crisis (of the 70's)... and of course the global cooling crisis (of the 70's)

Scientists may agree that temps are currently going up, but they know as much about what the future holds as they know about life on other planets.

I'm all for society being more responsible in terms of pollution and conservation... in fact I support any move away from petroleum fuels, whatever the excuse is that motivates the masses so be it; even believing an elaborate lie and acting on it is better than inaction... but the true threat to the world is to be found in our economic dependence on foreign oil, not the supposed global warming caused by burning those fuels.

Amen to the three above comments. To polarize this into a political issue and to belittle "global warming Cassandras" is to simply choose destruction over survival by never addressing the problem and blaming pea-brained fellow humans, all of whom are sunk and sinking unless we dramatically and quickly come up with non-COs emitting alternatives....Already hardly likely, but we should at least die fighting...We are indeed at a climate crisis, not because of what surface temperatures have or have not done before and after WWII, but because we currently have the highest human population EVER in the history of the earth, and the bulk of it is attempting to industrialize with completely unsustainable methods. The total of 500 million cars worldwide is unprecedented, and has almost doubled since 1998 alone—if it doubled in a mere 20 years, what is to happen in the next 20?

When I first learned to drive at age 16 in 1984, the majority of cars in the D.C. area not only obeyed traffic laws, but went below the speed limit, and people were actually ticketed for going 57 or 58. Now the trend towards utter lack of enforcement has led to absolutely lawlessness and flagrant disregard for all speed limits on every major highway and road, to the point that everyone feels they have to be aggressive in return just to survive. This trend is a huge failure of public policy....Similarly, we are accelerating our consumption of energy because of the complete lack of punishment or incentive for alternatives by either government, corporations, or bands of good citizens.

For the New York Times (my beloved Times, even though I am a lifelong native Washingtonian) to print such a foolishly polarizing statement, to insist that global warming is a political, not a survival issue, really wounds me. But perhaps a Fox fa**ist really did infiltrate the paper via some nasty web bug. Hallelujah that the Times provides such a revered and public forum so that Andrew Revkin is heard.

But ultimately I remain deeply pessimistic that so much damage has been done...Not merely population, but energy consumption, is so staggering it is beyond the capacity of any single pea-brained human to comprehend, let alone to change as quickly as we need to. I hug my young daughter as tightly as I can every day, I relish Chekhov and Turgenev as some of the only wisdom and consolation to the hopelessly ineffectual political and corporate and citizen avenues of change. We all just have one extremely short life, and it may quickly become much shorter for future generations. Enjoy blaming leftists or rightists or calling people alarmist as we all choke on polluted air and sink aboard the Titanic, if that is how you feel you need to live your short, brutish life. I would rather not only work to a real solution, but accomplish it.

Re: response of Mark Klein, M.D.

Dear Dr. Klein,

See number five, below:

The sort of leaders we need now are not those who promise ultimate victory over Nature through perseverance in living as we do right now, but those with the courage and intelligence to present the world what appears to

be Nature's stern but reasonable surrender terms:

1. Reduce and stabilize your population.
2. Stop poisoning the air, the water, and the topsoil.
3. Stop preparing for war and start dealing with your real problems.
4. Teach your kids, and yourselves, too, while you're at it, how to inhabit a small planet without helping to kill it.
5. Stop thinking science can fix anything if you give it a trillion dollars.
6. Stop thinking your grandchildren will be OK no matter how wasteful or destructive you may be, since they can go to a nice new planet on a spaceship. That is really mean and stupid.
7. And so on. Or else.

The conclusions are not supported by the data—the data is ANOMALIES, that is deviations from the period average, not the absolute temperature. Thus if the period average for 1934 (30 yr) is colder, a lower 1934 temperature will produce a higher anomaly. In fact, the global temperature index on the same site shows that the average around 1934 was much lower than the average around 1998: the conclusion is that 1998 was hotter.

In fact, if the factors producing random variation in temperature have not changed much, the anomalies should be evenly distributed over time, regardless of the trend.

NASA's corrected data shows that the last 9 years are consistently warmer than normal. There is no other non-overlapping 9-year period in the entire database since 1880 that is as warm as the most recent 9-yr period. If there is global warming it would be identified from a persistent warming over a long period. Nine years may not be long enough, to justify a definitive conclusion but a pattern such as this cannot be ignored. The fact that 1934 was warmer than 1998 is not valid support for denial of the onset of detectable global warming.

Dr. Klein: your argument about "technological fixes" would be easier to accept if the earth were not (unfortunately in context) a sphere. Yes, as the Earth warms, land may become arable further north, and substantial natural resources may become open to exploration.

The cold regions that will become warmer are relatively small. The hot ones that will become hotter are huge. When large sections of South America, Africa, and Asia become too hot to live in — and vast populations of impoverished refugees start migrating north and south into more developed countries — what "technological fixes" do you propose?

As I understand it, the argument for manmade global warming points out a cluster of recent years which are all among the warmest on record, not just a single blip in the data due to normal fluctuations as in 1934. The point is, if decreasing the manmade component in warming can reduce the overall severity of the warming and its negative consequences, we should do it. And as one reader pointed out, there are many other positive reasons to do so, such as decreasing our dependence on oil, which we need to do anyway before it runs out.

Climate change science is not (as skeptics seem to believe) like a "house of cards", ready to tumble down through a singular study or "data meltdown." Rather, climate change science is like a complex puzzle, many of the pieces having been firmly in place for over 100 years, becoming further resolved and assembled in the gradual process that is science. The pace of assembly has quickened substantially in recent decades to the point that the puzzle's essential landscape and image are clear. At most, a new study (or "data meltdown") may require that a piece or two need to be modified in shape or tint, but the basic picture being assembled remains firmly in place. It seems that the climate change "alarmists" are not the scientists who methodically spell out for us a very sobering picture of our future, lest we change, but those who think this well-grounded understanding of real processes may be overthrown through a singular and sudden bit of news. I wish it were so, but wishful thinking is not a solution in this case.

I don't get the spin on this one, it looks like a good example of scientific progress at work. one group points out an error in another group's work. the other group updates their method to account for it, and publishes the data. the essential hypothesis is still supported by the data—the trend is obviously significant for the US and the world, so what's the story here?

also, if you had any idea of what happened in 1934 (think dust bowl...), and the indication is that is the direction we are headed, maybe you wouldn't be so quick to jump on this one.

Even if this were true, which I doubt (come on, a Y2K bug? Please!), what is the point of focusing on the contiguous states of the USA? By surface area, that's only about 1.5% of the entire globe, after all. Check out this animation from NASA, and look at the BIG picture ...

http://www.giss.nasa.gov/research/news/20070208/169068main_temp_anom_w_date_320x240.mpg

Also, if you want to read a serious debunking of some of the dubious "scientific" methods practiced by Steve McIntyre and his pals, check here ...

<http://www.realclimate.org/index.php?p=121>

If only we could somehow sequester all the energy from the effort that people like McIntyre, the Bush admin., etc. put into disproving global warming, THEN we'd have our alternative energy source!

Jim

Thank you for sending this clarification. I also received the graphs from Makiko.

So is it correct to say that NASA's data is more accurate than NCDC's since it has more sources? In the media, it would be ideal to refer to one source rather than two. Traditionally we've used NCDC's data.

And globally, we usually use the Hadley Centre data...

Jim,

You could mention one other difference:

NCDC's curve is based exclusively on the 1221 closely examined and carefully corrected USHCN full data records, GISS's curve was culled from our GLOBAL analysis, i.e. from global maps produced by combining all available station records; this includes the part of the USHCN data that could be downloaded from USHCN's web site (ending currently with year 2005), but it also uses the remaining 541 US stations, and as far as the US mean is concerned, it is also impacted by the non-US stations located within 1200 km of the US border.

To: Rice, Doyle
Cc: Makiko Sato; Reto Ruedy; James Hansen
Subject: Re: USA temperatures - question from USA TODAY

Well, I guess that I would say it a bit differently.

Our method of analysis has features that are different than the analyses of the other groups. In some cases the differences have a substantial impact.

For example, we extrapolate station measurements as much as 1200 km. This allows us to include results for the full Arctic. In 2005 this turned out to be important, as the Arctic had a large positive temperature anomaly. We thus found 2005 to be the warmest year in the record, while the British did not and initially NOAA also did not. Independent satellite IR measurements showed that our extrapolations of anomalies into the Arctic were conservative. I am very confident that our result was the correct one in that instance.

Also, as we show in our 2001 paper, our urban warming correction in the U.S. differs from the NOAA correction (we have a larger adjustment, which decreases recent temperatures relative to last century). I would not claim that one is superior to the other, but the different results provide one conservative measure of uncertainty. In general it has proven very useful to have more than one group do the analysis.

Also it should be noted that the different groups have cooperated in a very friendly way to try to understand different conclusions when they arise. You will see that we had co-authors from the other groups on our 2001 paper. And in general it is a bad idea to anoint any group as being THE authority. Science doesn't usually work best that way.

Jim

On 8/29/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:
Doyle,

Since this is a technical question and Dr. Hansen is busy this afternoon, I'll answer it:

No, your statement is NOT correct; to get the US means, NCDC's procedure of only using the best stations is more accurate. If that were our goal, we would proceed in the same way. Actually, whenever we report on US means in our publications, we recompute all US means using only USHCN data.

My recommendation to you is to continue using NCDC's data for the US means and Phil Jones' data for the global means. Our method is geared to getting the global mean and large regional means correctly enough to assess our model results.

We are basically a modeling group and were forced into rudimentary analysis of global observed data in the 70's and early 80's since nobody else was doing that job at the time. Now we happily combine NCDC's and Hadley Center's data to get what we need to evaluate our model results. For that purpose, what we do is more than accurate enough. But we have no intention to compete with either of the other two organizations in what they do best.

Sincerely,

Reto

Dear Dr. Hansen, Dr. Ruedy and Dr. Sato,

I want to express my appreciation for your making available the source code for your surface temperature data analysis. Thank you very much your time and effort last week in compiling and annotating the computer programs.

Best regards,

UC Berkeley (graduate student)

CC: "Reto Ruedy" <cdrar@giss.nasa.gov>, "Makiko Sato" <makis@giss.nasa.gov>

Dear Dr. Hansen,

Thank you very much for your quick reply. I look forward to seeing the code.

As it happens, I frequently use Python (in particular, the SciPy and Numeric Python packages) in my own data analysis projects. I think it is one of the best available programming environments for data processing, and I would heartily recommend it. Much of it is very similar to Matlab, which you may be more familiar with.

Best regards,

On 9/4/07, James Hansen <jhansen@giss.nasa.gov> wrote:

You are welcome to have a copy of our computer code. Depending upon your programming background, there is a possible small complication in that parts of the computer program as it is used were written by a person (Jay Glascoe) who left several years ago in a code (Python) that is obscure to most of us (perhaps all of us at GISS). Reto Ruedy is in the process of rewriting that part in Fortran, as we know the function of it; and the Python and Fortran codes should give the same results. In the interim, we will release the codes as they have been used (including Jay's Python subroutines). The procedure to access the codes will be described in my next e-mail, which I will send this week.

Jim Hansen

(By the way, Reto also notes that the codes are a collection that accumulated over 25 years. Actually, I started with an NYU undergraduate student in the 1970s, but Sergej Lededeff replaced most of that code in the early 1980s. Reto says that he intends to simplify/combine steps in the code, but it may be several weeks before he can do that.)

On 9/4/07, @socrates.berkeley.edu> wrote:

Dear Dr. Hansen,

My name is and I am a graduate student in physics at UC Berkeley. I am writing to request the complete computer program source code you and your coauthors used to adjust and analyze the surface temperature data in the following paper:

Hansen, J., Mki. Sato, R. Ruedy, K. Lo, D.W. Lea, and M. Medina-Elizade 2006. Global temperature change. Proc. Natl. Acad. Sci. 103, 14288-14293,
<http://www.pnas.org/cgi/content/abstract/103/39/14288>

I and others would like to understand all details of your analysis of global temperature trends. I am making this request for source code consistent with the PNAS policy copied below.

Thank you very much in advance.

Sincerely,

berkeley.edu

PNAS policy from

<http://www.pnas.org/misc/iforc.shtml#policies>

(viii) Materials and Data Availability. To allow others to replicate and build on work published in PNAS, authors must make materials, data, and associated protocols available to readers. Authors must disclose upon submission of the manuscript any restrictions on the availability of materials or information.

Authors must make Unique Materials (e.g., cloned DNAs; antibodies; bacterial, animal, or plant cells; viruses; and computer programs) promptly available on request by qualified researchers for their own use. Failure to comply will preclude future publication in the journal. It is reasonable for authors to charge a modest amount to cover the cost of preparing and shipping the requested material. Contact pnas@nas.edu if you have difficulty obtaining materials.

Subject: GISS data update

Any idea what the "average height above ground" is for the temp reporting stations that feed raw temp data to your models?

Any idea of "concrete/man-made surface mass" increase or decrease in and around temp reporting stations over the last 30 years?

Jim,

The only factual inaccuracy is the years affected by the discontinuity:
So I would change Jack's sentence that starts with:

"The flaw affected only ..."

I would replace the end "and only after 2000" by "and only for years
2000-present"

or something like that.

Don,

These are some desperate characters trying to make a mountain out of a mole hill.

I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw.

We also point out in that

To: "James Hansen" <jhansen@giss.nasa.gov>

Dr. Hansen,

You were very kind to take the time to answer my questions about the global warming model. In turn I would like to extend a hand of friendship and invite you to come to Des Moines Iowa on October 21st. We're putting together a rally and concert to encourage Al Gore to enter the presidential race because we believe there is no better leader out there and we need him. Many grass roots and "netroots" groups from across the country have come together to make this effort a reality. We would be honored if you would participate.

The event will be held at the Hoyt Sherman Center, a venue that includes a theater that seats around 1200 people. We are actively recruiting others to participate and will be publicizing the event widely next week. Among others, the event will showcase a young inventor, Chris Olsen, and his wave energy converter to demonstrate high-yield, low cost solutions to the global warming crisis.

Please take a moment to visit the virtual center where the rally and concert will be held:

<http://www.hoytsherman.org/virtual.html>

Please say you'll come to our "Run, Al, Run" rally and concert.

Subject: Fwd: A Light On Upstairs?

Your e-mail should be framed, as a counterweight to the all the viscous ad hominem e-mails that have descended through the ethernet.

The answer to your first question is in the attachment. You will see that the flaw in the analysis was of a sort that might occasionally happen, without being detected for a while because the effect is so small. (The large effect claimed in some of the hate-mails was apparently due to some people confusing conclusions about which year was warmest in the United States and which year was warmest on the global average.)

The answer to your second question is that this matter has no effect whatever on climate models or the interpretation of results from climate models, as you can infer yourself once you have looked at the response to your first question.

Jim Hansen

Dear Dr. Ruedy,

I see what you mean. It is likely that my previous attempt to read the file (via a program) failed but that I did not catch the error in the log. At the time, the program would write a seemingly valid summary, which is why I thought I had a successful read previously. I thought I had caught all of those, but apparently I did not. I have since corrected the program's behavior.

Thank you,

Reto Ruedy wrote:

Dear Mr.

Ostrov Dikson (22220674000) seems to work fine again.

However, I can't believe that you ever could display Kronstadt (63826063001) since the only data GHCN has for that station are from 1844-1875 - and we only use data starting in 1880. Do you remember the name of the station that you displayed ?

Subject: Re: Preliminary examination of HL87 bias method as applied to individual station records

Dear Dr. Hansen,

I agree - my first impression is that impact to absolute temperature appears to be small, as is seen in the plot I sent. What I have not tried to look at yet is how it affects the anomaly and resulting trend line. I noticed that the period 1951 to 1980 has a relatively large negative bias, which I found surprising. When I first started thinking about this from a pure mathematical sense I was expecting the largest bias to be in the earliest years and decreasing as it approached 1991. To find the reverse to be true was a surprise.

I think two things are at play in producing the results I found. One is certainly the order records are combined. I have found many examples where a simple swap in records has a big impact on bias across multiple records. In fact, the original implementation used to emulate the algorithm had a bug that improperly ordered records when no MCDW record existed. The plot I produced showed a slight positive bias overall!

The second thing that comes into play is the estimation of missing quarterly and annual values. The overlap period between the MCDW and other records is almost always four years, sometimes five. The first annual average in an MCDW record is always an estimate, because the previous year's December temperature is not available. I have found multiple cases where the monthly averages between an MCDW record and another record are identical, but the estimated first annual average for MCDW differs from the measured average in the other record. Because of the short overlap period, this estimate has significant influence on the bias magnitude applied to the other record.

This is why, in part, I suggested that estimation be done after records are combined rather than before, because the estimation process influences the combination process. I also think that the greater number of data points one gets by measuring overlap at the monthly level rather than annual level yields a more robust combined record.

Regards,

James Hansen wrote:

Hi

Thanks for the comments and suggestions. I spoke briefly with Reto. He has looked into the routine written by Jay Glascoe to combine records, and although its a language he is not familiar with, he says that he can at least make the simple changes needed to test the ordering of stations. Since we tested the ordering of stations in the main part of the program (we are not sure whether Jay rechecked that), we doubt that it would make a noticeable difference, but will let you know.

We didn't have time to discuss the other things yet. But I note that tests in the past have shown such choices to have small impact.

Regards, Jim Hansen

@charter.net> wrote:

Dear Dr. Hansen,

I understand you are extremely busy, but I wanted to pass along some analysis I have been doing on your method of combining individual temperature records for a single station using the "bias method", as described primarily in HL87.

My preliminary analysis of the method seems to show that it introduces an "artificial cooling" to station records before 1987. This cooling seems to be introduced primarily as a result of two things: the order selected for combining records and the fact that annual and quarterly temperatures are estimated prior to combining those records.

In HL87 you acknowledge: "One potential disadvantage of the method we have described for combining station records is that the results, in principle, depend on the ordering of the station records." However, the discussion that ensues is around different stations rather than different records for the same station. I am finding that, when using this method to combine records from a single station, the ordering of records has far more influence than expected.

The descriptions I have seen for ordering stations in your papers indicate that they are ordered from greatest number of years of temperature record to the least number of years. In practice what I find is that if an MCDW (Monthly Climatic Data for the World) record exists, it is used first, even though it is usually the shortest record (when it exists, it also the latest record for a station). Because it is the first record in the order, it is never biased, but all others preceding it chronologically are biased. The overlap period with preceding records seems to be somewhat short - usually four years, sometimes five. Although HL87 discusses the combination of stations within a gridcell, the implication is that the same methodology is used for combining station records. This would mean the minimum overlap period should be 20 years.

In reading HL87 I would have expected the period of overlap to be calculated using the months of overlap, which represents the finest grain of measurement in the record GISS uses. Instead, I have determined that the annual record is used, which is the coarsest grain of measurement in the record used by GISS. If the monthly records were complete, this would not be an issue. In practice I find that they are usually not complete, so an estimated annual average is often used when determining overlap periods. In fact, the first year in a record is almost always an estimate. This is because the records begin in January, but the average is calculated from December to November. Thus, the "missing" December value must be estimated. The process of estimating annual averages prior to combining individual records for a station is not one that I have found documented thus far.

As chance would have it, the process of combining records using MCDW records first, the short overlap period between MCDW records and previous records, and the fact that many annual averages are estimated, seems to yield a clear cooling bias to pre-1991 temperature records. An example can be seen here with the Russian records.

While I understand the rationale behind using the bias method to combine station records within a grid cell, I don't fully understand why it is used to combine separate records for an individual station. As you note in your 1999 paper "in the majority of cases the overlapping portions of the two records are identical, representing the same measurements that have made their way into more than one data set." This indicates that a simple average

of the records is appropriate.

Why is the bias method better than the following?:

- For each station examine all monthly records for the station simultaneously
- If no valid measurement exists in any record for a given month, record NA (or equivalent)
- If exactly one valid measurement exists for a given month, use that value
- If more than one valid measurement exists for a given month, use the average of all valid measurements

After all records have been combined in this manner, estimate missing annual values where possible.

I appreciate your thoughts on this.

To: Reto Ruedy
Subject: Station ID 62103970000

Good morning Dr. Ruedy,

My program choked when I tried to process the data for record 6 of station 62103970000 (the last of seven records for the station). When I looked at the record on GISS I noticed the entire record is as follows:

YEAR	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC	D-J-F	M-A-M	J-J-A	S-O-N
ANN																
1993	999.9	999.9	999.9	999.9	999.9	999.9	14.0	13.4	11.6	7.5	5.8	999.9	999.9	999.9	13.7	8.3
999.90																
1994	5.0	4.2	6.8	999.9	10.1	999.9	14.6	999.9	999.9	999.9	999.9	999.9	4.6	8.5	999.9	999.9
999.90																

The question I had was, since there is very little data in this record and no annual average can be estimated, is this a useful record?

(This is a harmless question - I am just curious)

Thanks,

Subject: Re: Station ID 62103970000

Dear Dr. Ruedy,

Thank you for explaining what happens with the Claremorris MCDW record after step 1. Dropping it makes sense.

In my previous email to Dr. Hansen I think I over-emphasized the ordering used to combine records and thus masked what I believe is really at the heart of the matter. That is, identifying records that are variations of each other and then properly combining them. By "properly combining" I mean to suggest the use of one or more algorithms that are not dependent on station order (the ideal algorithm is mathematically commutative).

Also, I think that any combining method should work at the monthly level rather than the annual level. The overlap period between two records is often very short, and the use of annual averages provides poor granularity for applying a combining algorithm. Plus, the annual averages are very often estimated, as I noted in my previous email, and I think that exposes the combining method to using corrupt data. In fact, the bias method seems particularly sensitive to the use of estimated annual averages. Using monthly data as input should lessen that exposure.

I have not done a thorough analysis of all Russian records but I have noticed in spot-checks that many records are identical or near-identical during the period of overlap. Dr. Hansen makes mention of this observation in HL87. If they differ it is often by 0.1 or 0.2 degrees. In the case of such records I intuitively think that the proper method for combining the records is to average them month by month. When a monthly value exists in one record but not the other, use the existing value. When a monthly value does not exist in either record, it should not exist in the combined record. Annual averaging can be done after all records are combined. This approach would be mathematically commutative and does not depend on estimating missing values. I think most, if not all, records with short overlap intervals can be combined in this manner.

Longer records can be more complicated. I have noticed time periods within longer overlap periods that are identical or near identical. Thus, for those time periods I would combine the data as described above. Other time periods may require some form of adjustment prior to combining, but I do not presently have a sound suggestion as to how that should be done. I have seen odd patterns of differences between some records that defy a suggested method of combining them. For example, Bratsk record 0 and record 1 overlap from 1951 through 1990. Looking at the period from 1951 to 1965, I see an interesting pattern of differences on a month-by-month basis. Subtracting record 0 from record 1, I see that most (not all) differences are as follows:

Jan - 0
Feb - 0
Mar - -0.2
Apr - 0
May - +0.2
Jun - +0.3
Jul - +0.2
Aug - +0.1
Sep - -0.1

Oct - 0
Nov - 0.1
Dec - 0.1

Perhaps, at the end of the day, the different records for a single station should simply be averaged during the period of overlap as described above, since the assumption is that they are co-located?

Kind regards,

Reto Ruedy wrote:

Good morning

In our procedure, the MCDW record of Claremorris (Ireland) survived (barely) step 1 as an individual series, since it was too short to be combined with the other sources.

It got dropped at the beginning of step 2 together with all records that did not contain at least 20 years of data.

For our purpose, this record had no use. More generally, records shorter than 4 years are not used by our procedure; if it helps to keep your program from crashing, you may as well disregard them right away.

By the way, I did carry out the analysis combining sources in the order of their length (rather than starting with MCDW). It caused a slight but insignificant increase in the temperature trend. The individual global annual means were affected by -0.003C (1910-1920) to $+0.005\text{C}$ (1995-present), whereas the margin of error is of the order of magnitude of 0.1C .

When Dr. Hansen comes back from travel, he will decide how much of this analysis will be put on the web.

As you see from your own mail, all GHCN data are rounded to the nearest tenth of a degree. So there is no point worrying about procedural modifications that affect station data anomalies by less than $.1\text{C}$. At the end of step 1 and step 2, we again round the data to the nearest tenth of a degree.

At the beginning of step 3, we subtract from each time series its 1951-1980 mean, hence any vertical shifts introduced by the "bias method" in step 1 will cancel out at that point.

Thanks for your interest,

Reto A. Ruedy

Dear Leslie,

My fellow Canadians have unveiled another Global warming scam - yours!

Now that we know Mr. Hansen used incorrect data or procedures in determining the "hottest years", concluding that the top 5 warmest yeats since the 1890s are : 2005, 1998, 2002, 2003, 2006.

Yet, there on your website (<http://www.giss.nasa.gov/research/news/20070208/>) is the information still making what is now known to be a bogus claim.

Yes we are at a tipping point all right. And the truth is spilling all over your pro-AGW agenda.

Just like Mr. Manns infamous Hockey Stick graph, which was proven fraudulent by the same people who found your glaring errors, another lie bites the dust. Funny thing is, when they determined Mr. Mann was fudging things, they found that Mr. Mann's "peer reviewed" work was reviewed but not put through a rigourous, truth seeking, audit. That led to them forming climateaudit.org, to apply the audits that are so obviously missing from the process. And BINGO - Mr. Hansen is unmasked as a zealot.

Now, are you honestly a scientific driven institution, or will you admit to being an agenda driven one? I await the press conference to announce that you have had to revise the hottest years list. I await the update to your website to reflect the new, peer-audited, results. I await the confession that you made a huge mistake. I await the firing of those who created and flogged this lie.

Will you do the right thing?

Sincerely

Jim,

Earlier I sent the following to Gavin -- and I realize that these are points you've been repeating for many years, just want to add that EarthObservatory could be helpful to get the word out:

Yes, I agree that this could be an educational opening for mainstream media.

My feeling is we need to lead with some of the faulty claims, and then illustrate that:

- (1) the data is all freely available and widely used for scientific study;
- (2) scientists use extensive statistical testing to determine whether observed differences can be ignored as being within the observational uncertainty or natural year-to-year variations;
- (3) changes of a given magnitude at a station or in a limited area average like the lower 48 contiguous United States, which covers about 2% Earth's surface, are less likely to be significant than a change of similar magnitude in averages over the full surface area of the Earth, which is less affected by many local influences (mention corrections to minimize urban effects too); and
- (4) changes in individual years, even ones that change the ranking of years, are less likely to be associated with sustained climate change than changes averaged over several successive years. On

this last point we might quote the CCSP temperature synthesis and assessment product 1.1, which emphasized this point.

Of course these are all basic points that any of us climatologists know, but the public needs reminding, and this brouhaha could give a good opportunity to educate any "fence-sitters" who might be listening...

.Bob.

Jim,

We can't spare much time either. I have 10 years to go, by the way! I hope the Met Office predictions for 2015 in last week's Science are correct!

I don't think I'm keeping fully on top of all the things going on with the network around the world. As I think you might have said earlier, we aren't doing a great job measuring surface T in a consistent manner. Loads of automation in many countries and now these issues with the marine data. Possible urbanization is the only thing with the land that might matter. I'll be doing some work on that next year.

On the SSTs, we don't do much here, but the HC people think it isn't much of an issue. NCDC does though hence their paper, which when it comes out will just open up this whole debate again about record years. Our error ranges circumvent a lot of this - showing as they do that the second decimal place shouldn't be relied upon. We're only measuring to an accuracy of 0.1.

I guess if you'd rounded to tenths none of the comments of the last few days would have happened. Our files work the numbers out in thousandths, but we round these for the web!

Keep up the good work all round!

I was looking for something a few months ago and I found that cheque from Hugh Elsasser!

Cheers

Phil

At 15:12 15/08/2007, James Hansen wrote:

Hi Phil,

Thanks, this is very helpful. Glad that you are keeping on top of these things -- we can only give a small fraction of our time to this topic, so it is good that someone keeps on top of it. By the time you are ready to retire global warming may be large enough that it doesn't require that level of expertise and detail. I am especially interested in your comments about NOAA SSTs -- they seemed just a hair cool to me.

> Jim, Gavin,

Your recent finding of NCDC/GHCN not continuing to adjust records in real time and its impacts on blog sites, has alerted me to inform you of a few things

we've been doing over the past year. Don't pass any of this on via Real Climate or whatever. Eventually, we will get around to documenting all we've been doing.

1. You may have noticed that Canada has changed loads of its WMO IDs. We've been in contact with Lucie Vincent there who's also been doing some homogeneity work (which is good by the way). As a result of this we are applying adjustments in real time to about 40 stations (mainly in the east of the country) in order to use her long adjusted series. Why she adjusted records to an earlier period still isn't clear to me. We are also getting on top of their station number changes, which appear related to automation - and giving the new AWSs a new number.

By the way the AES web site enables you to get their real time data, but there is no mention there of another page which gives the homogeneous series!

This is all less important with your method of combination. Ours requires normals.

2. We're getting all Australian data in real time direct from the National Climate Centre in Melbourne.

3. We've got all the long NZ series they have homogenized.

Problems with both Australia and NZ associating these with WMO IDs we had.

Why it's always the English speaking countries is odd? Maybe this is because we can find out/understand more easily what they're doing!

4. My biggest worry is China. CMA don't measure at airports, and they keep moving suburban locations a few more miles out as the cities expand. I was there a month ago to give some talks. I've sent them all the CRU data for China, in the hope that they will reciprocate at some point and send me their adjusted data (for site moves, but not urban influences). They are doing some reasonable work, but not seeing the big picture...

Other issues:

1. I reviewed a paper by NCDC (Smith/Reynolds/Peterson) recently. It was OK, but when it comes out it will raise the whole debate again. SSTs are being increasingly measured by buoys (drifting and fixed) and they now dominate over the ships. It seems they are about 0.1-0.2C cooler over the ships. So NCDC will be increasing global temps from about 2000 onwards.

Gavin, Jim,

For some reason the Guardian has run with the story - NASA caught out by blogger. I've just spoken to two other papers - Times and the Mail on Sunday. I think I persuaded the former this was a storm in a tea cup, but the Mail on Sunday is generally big on conspiracies, so may not have there.

Cheers

Phil

Jim,

We can't spare much time either. I have 10 years to go, by the way! I hope the Met Office predictions for 2015 in last week's Science are correct!

I don't think I'm keeping fully on top of all the things going on with the network around the world. As I think you might have said earlier, we aren't doing a great job measuring surface T in a consistent manner. Loads of automation in many countries and now these issues with the marine data. Possible urbanization is the only thing with the land that might matter. I'll be doing some work on that next year.

On the SSTs, we don't do much here, but the HC people think it isn't much of an issue. NCDC does though hence their paper, which when it comes out will just open up this whole debate again about record years. Our error ranges circumvent a lot of this - showing as they do that the second decimal place shouldn't be relied upon. We're only measuring to an accuracy of 0.1.

I guess if you'd rounded to tenths none of the comments of the last few days would have happened. Our files work the numbers out in thousandths, but we round these for the web!

Keep up the good work all round!

I was looking for something a few months ago and I found that cheque from Hugh Elsasser!

Cheers

Phil

At 15:12 15/08/2007, James Hansen wrote:

Hi Phil,

Thanks, this is very helpful. Glad that you are keeping on top of these things -- we can only give a small fraction of our time to this topic, so it is good that someone keeps on top of it. By the time you are ready to retire global warming may be large enough that it doesn't require that level of expertise and detail. I am especially interested in your comments about NOAA SSTs -- they seemed just a hair cool to me.

So NCDC will be increasing global temps from about 2000 onwards.

2. SSTs are now coming in for the areas losing Arctic sea ice. The normals we have for these are -1.8C which is completely wrong. Shortish time series

are composed of entirely positive anomalies. Maybe this is true, but it probably shouldn't be as much as it is. This problem will get worse as the sea ice continues to go. Your use of land only data shouldn't have the problem.

The SST issues highlight that it is the biases (bucket/intakes and urbanization)

that are important as they are potentially pervasive. Individual station homogeneity issues cancel as sites are all affected differently. Getting this right has hardly any effect (none in fact) on the large-scale averages. Might affect smaller regions, and it's good to get as many right as possible, as the deniers will claim if one is wrong the whole lot is wrong. The law of large numbers seems to be totally forgotten by those collecting pictures of sitings across the US. Still it gives them something to do...

Cheers

Gavin,

It seems that Telegraph and also Radio4 ran with the story. Got up as usual at 6.45 turned on the Radio. Immediately got McIntyre - too much that early in the morning!

I see you're trying to respond on RealClimate. Saw a comment about the UK summer. Here's the CET figures

June 15.1 +0.9 wrt 61-90

July 15.2 -0.8

Aug (to15th) 16.3 +0.3

So far, therefore, it has been above normal - just. Nowhere near as bad as the year without a summer in 1816 (that had a JJA average of 13.4). By the way 1725 and 1695 were even colder at 13.1 and 13.2! People seem to adapt quite quickly to a degree of two increase and expect all seasons/years to be above.

If CET is at least 1.15 C above for Aug16-Dec31 we will break the 2006 record.

OK, it has been wet, but not everywhere. Scotland has had less precip. We're almost bang on normal here in Norwich !

Cheers

Hello all, Dale Kaiser of CDIAC here.

For the GUIs CDIAC has prepared for obtaining USHCN data, we intentionally are only using data through the last complete year available, whereas, like Jay says, I'm sure that NCDC has files that go through the last month they have ready for distribution.

Dale

On Thursday 13 September 2007 11:41 am, Reto Ruedy wrote:

Hi Jay,

Thanks for your quick and helpful response - starting from USHCN's home page, I ended up at <http://cdiac.ornl.gov/ftp/ushcn/monthly> where the data are cut off at the end of 2005.

Reto

On Thu, 2007-09-13 at 11:05 -0400, Jay Lawrimore wrote:

Hi Reto,

It is ok with us if you make the old USHCN file publicly available. For the most recent data we have online you can go to <ftp://ftp.ncdc.noaa.gov/pub/data/ushcn/> . That has been updated through October 2006.

Regarding old versions of files - Claude Williams recently responded to a request for USHCN data from the 1980s. He attempted to reproduce the data but I'm not sure he was successful. To answer your question - we do our best to provide the data requested but we have not archived all data files along the way.

I will ask Claude if he can respond to your 4th question.

Jay

Reto Ruedy wrote the following on 9/13/2007 9:37 AM:

Hi Jay,

Recently, we replaced - for our temperature analysis - the USHCN data you gave us back in 2000 (last stage before filling in missing data) by the file "hcn_doe_mean_data" (ending in 2005). Needless to say, this had little impact on our global analysis.

Recently, we have been approached by Steve McIntyre and his fans; in particular, he now is questioning some differences that originate in differences between the two USHCN files. He keeps insisting on seeing all our programs and input files, and I'm sure he bothered you - or whoever is in charge of USHCN now - with similar requests.

Four questions:

- 1 - Would it be ok with you if we made the old USHCN file publicly available ?
- 2 - Steve claims that USHCN data are publicly available to the end of 2006 - is that true and if so, where can I find it ?
- 3 - One person invoked FOIA to demand the release of the original temperature files that were used in 1999 as basis of one of our papers. Since you probably got similar requests, how do you respond ? Do you really keep for ever any files that were used in any of your papers ?
- 4 - Is using "hcn_doe_mean_data" disregarding any filler for missing data (marked M) a legitimate use of that file, and is this equivalent to using the SHAP version ?

Reto,

While I am basically a user of USHCN (not a real expert like several NCDC folks), and CDIAC just emphasizes trying to make it easy for users to get the data, I will say that I've not read about any additional processing steps in between the SHAP and FILNET stages. But again, Claude, Matt, Jay, et al. at NCDC are best to ask about such details.

Best wishes,

Dale

On Thursday 13 September 2007 12:20 pm, Reto Ruedy wrote:

Hi Dale,

Thanks for your input; for our purposes, it doesn't matter where exactly the data stop, since GHCN will always be ahead of USHCN, and I hope Jim will agree to go with an annual update as far as the USHCN data are concerned.

In 2000, we used the last stage (TOBS+MMTS+SHAP corrections) before the filling in and homogeneization steps of USHCN. I did not want to bother you each time to get that version, especially since I noticed that the filled in data are marked. So I thought, it would amount to the same if I just disregarded those data. Just want to make sure, I'm not missing any other changes that were made going from SHAP to FILNET.

Thanks,

Reto

Jim - thanks for sending this to me.

We have an action to respond to a Congressional question about this. Can you provide us with a relatively straightforward answer (with some #) that we can transmit? I don't think we need anything extensive or complex, but a relatively brief (but quantitative) "just the facts" summary would help. As a backup, it may be good if we could have some # in case we get asked for more detail (e.g., list of top 20 warm years, time series of global T for last 15 years and also for 1934 +/- 5 years).

Don is on travel, but may be checking e-mail.

Time scale is, of course, asap! - Jack

On 8/14/07 2:52 AM, "James Hansen" <jhansen@giss.nasa.gov> wrote:

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intent of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected by adding the NOAA/NCDC adjustment near the end of the record to the 2001-2007 data, and it has been so corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the *Washington Times* (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com <<http://climateaudit.com>>

labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

On 8/15/07 2:27 AM, "James Hansen" <jhansen@giss.nasa.gov> wrote:

Jack, I am writing something, with figures, which I will send later today. Here are a few relevant paragraphs for now. Jim

The computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001). The flaw affected temperatures only in the United States and only after 2000.

[As explained in the e-mail sent out last week, one of the improvements made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the United States as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day at which measurements were made, etc. Our computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in the temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on XX July 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000.

Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

Jim - thanks for sending this to me.

We have an action to respond to a Congressional question about this. Can you provide us with a relatively straightforward answer (with some #) that we can transmit? I don't think we need anything extensive or complex, but a relatively brief (but quantitative) "just the facts" summary would help. As a backup, it may be good if we could have some # in case we get asked for more detail (e.g., list of top 20 warm years, time series of global T for last 15 years and also for 1934 +/- 5 years).

Don is on travel, but may be checking e-mail.

Time scale is, of course, asap! - Jack

On 8/14/07 2:52 AM, "James Hansen" <jhansen@giss.nasa.gov> wrote:

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intent of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected by adding the NOAA/NCDC adjustment near the end of the record to the 2001-2007 data, and it has been so corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. *In an op-ed for the Washington Times (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.*

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com <<http://climateaudit.com/>> labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be

corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

Jim - in attempting to close the loop on this so we can deal with the legislative action, I wanted to see if we could come up with any more quantitative information. I looked at the longer text that you had the link to ("The Real Deal: Usufruct & the Gorilla).

First, it appears that the "XX July 2007" in your message below should be 7 August 2007.

In terms of 1934 vis a vis the more recent years, the key data I see from your text that may be worth citing are:

- The four warmest US years on record were 1921, 1934, 1998, and 2006
- The mean temperature anomaly in the US was 1.25 deg C in 1934 and 1.13 deg C in 2006, which is the ~ 1/10 degree difference between the two, which is smaller than the uncertainty in the actual numbers.
- In 1934 the US was warm relative to much of the rest of the world, while in 2006 the world was much warmer.

If these points are enough, we can try to get them into a short paragraph. How about this?

The computer program used by Dr. Hansen to create the temperature record is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen in a peer-reviewed publication from 2001. The flaw affected temperatures only in the United States and only after 2000. As explained by Dr. Hansen in an e-mail sent out on August 10, one of the improvements made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the United States as adjusted by Thomas Karl of NOAA's National Climatic Data Center and his colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day at which measurements were made, etc. Dr. Hansen's computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and his computer program picked up the data for these same stations reported in the World Meteorological Organization's GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in the temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISS Temperature web page. Based on the current analysis, the four warmest years in the US record were 1921, 1934, 1998, and 2006. The mean temperature anomaly in the US was approximately 1/10 degree C greater in 1934 (1.25 degrees) than in 2006 (1.13 degrees); this difference is less than the uncertainty in the calculated mean. One point worth noting is that in 1934, the US was warm relative to much of the rest of the world, while in 2006, the warmth of the US was accompanied by that of much of the globe.

Would you be okay with this? If not, do you have suggestions? I don't know that we'd need much more than this!

Jim - thanks for sending this to me.

We have an action to respond to a Congressional question about this. Can you provide us with a relatively straightforward answer (with some #) that we can transmit? I don't think we need anything extensive or complex, but a relatively brief (but quantitative) "just the facts" summary would help. As a backup, it may be good if we could have some # in case we get asked for more detail (e.g., list of top 20 warm years, time series of global T for last 15 years and also for 1934 +/- 5 years).

Don is on travel, but may be checking e-mail.

Time scale is, of course, asap! - Jack

On 8/14/07 2:52 AM, "James Hansen" <jhansen@giss.nasa.gov> wrote:

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.)

was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw.

We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intent of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected by adding the NOAA/NCDC adjustment near the end of the record to the 2001-2007 data, and it has been so corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the Washington Times (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn

out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com <http://climateaudit.com/> <http://climateaudit.com/> labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and

2006.

Subject: Re: USHCN temperatures

From: Jay Lawrimore <Jay.Lawrimore@noaa.gov>

Date: Thu, 13 Sep 2007 11:05:24 -0400

To: rruedy@giss.nasa.gov

CC: James Hansen <jhansen@giss.nasa.gov>, cdiac@ornl.gov, Claude N Williams <Claude.N.Williams@noaa.gov>, Matthew Menne <Matthew.Menne@noaa.gov>, David Easterling <David.Easterling@noaa.gov>, Thomas C Peterson <Thomas.C.Peterson@noaa.gov>

Hi Reto,

It is ok with us if you make the old USHCN file publicly available. For the most recent data we have online you can go to <ftp://ftp.ncdc.noaa.gov/pub/data/ushcn/> . That has been updated through October 2006.

Regarding old versions of files - Claude Williams recently responded to a request for USHCN data from the 1980s. He attempted to reproduce the data but I'm not sure he was successful. To answer your question - we do our best to provide the data requested but we have not archived all data files along the way.

I will ask Claude if he can respond to your 4th question.

Jay

Reto Ruedy wrote the following on 9/13/2007 9:37 AM:

Hi Jay,

Recently, we replaced - for our temperature analysis - the USHCN data you gave us back in 2000 (last stage before filling in missing data) by the file "hcn_doe_mean_data" (ending in 2005). Needless to say, this had little impact on our global analysis.

Recently, we have been approached by Steve McIntyre and his fans; in particular, he now is questioning some differences that originate in differences between the two USHCN files. He keeps insisting on seeing all our programs and input files, and I'm sure he bothered you - or whoever is in charge of USHCN now - with similar requests.

Four questions:

- 1 - Would it be ok with you if we made the old USHCN file publicly available ?
- 2 - Steve claims that USHCN data are publicly available to the end of 2006 - is that true and if so, where can I find it ?
- 3 - One person invoked FOIA to demand the release of the original temperature files that were used in 1999 as basis of one of our papers. Since you probably got similar requests, how do you respond ? Do you really keep for ever any files that were used in any of your papers ?
- 4 - Is using "hcn_doe_mean_data" disregarding any filler for missing data (marked M) a legitimate use of that file, and is this equivalent to using the SHAP version ?

Steve McIntyre, of Toronto operates www.climateaudit.org and began to investigate the data and the methods used to arrive at the results that were graphed by NASA's Goddard Institute for Space Studies (GISS).

What he discovered was truly amazing. Since NASA does not fully publish the computer source code and formulae used to calculate the trends in the graph, nor the correction used to arrive at the "corrected" data. He had to reverse engineer the process by comparing the raw data and the processed data..

Here is one of his first posts where he begins to understand what is happening. "This imparts an upward discontinuity of a deg C in wintertime and 0.8 deg C annually. I checked the monthly data and determined that the discontinuity occurred on January 2000 - and, to that extent, appears to be a Y2K problem. I presume that this is a programming error."

He further refines his argument showing the distribution of the error, and the problems with the USHCN temperature data. He also sends an email to NASA GISS advising of the problem.

He finally publishes it here, stating that NASA made a correction not only on their own web page, attributing the discovery to McIntyre, but NASA also issued a corrected set of temperature anomaly data which you can see here:

<http://data.giss.nasa.gov/gistemp/graphs/fig.D.txt>

Steve McIntyre posted this data from NASA's newly published data set from Goddard Institute of Space Studies (GISS) These numbers represent deviation from the mean temperature calculated from temperature measurement stations throughout the USA.

According to the new data published by NASA, 1998 is no longer the hottest year ever. 1934 is.

Four of the top 10 years of US CONUS high temperature deviations are now from the 1930s: 1934, 1931, 1938 and 1939, while only 3 of the top 10 are from the last 10 years (1998, 2006, 1999). Several years (2000, 2002, 2003, 2004) fell well down the leaderboard, behind even 1900. (World rankings of temperature are calculated separately.)

Top 10 GISS U.S. Temperature deviation (deg C) in New Order 8/7/2007

Year	Old	New
1934	1.23	1.25
1998	1.24	1.23
1921	1.12	1.15
2006	1.23	1.13

1931	1.08	1.08
1999	0.94	0.93
1953	0.91	0.90
1990	0.88	0.87
1938	0.85	0.86
1939	0.84	0.85

Here's the old order of top 10 yearly temperatures.

Year	Old	New
1998	1.24	1.23
1934	1.23	1.25
2006	1.23	1.13
1921	1.12	1.15
1931	1.08	1.08
1999	0.94	0.93
1953	0.91	0.90
2001	0.90	0.76
1990	0.88	0.87
1938	0.85	0.86

I salute the work of Steven McIntyre, he has now made two major contributions to climate science.

- 1) Proving how the Mann "hockey stick" used in all Gore's movie, An Inconvenient Truth, was based on unsupportable data and methods.
- 2) Proving how yearly temperature anomalies for the USA are based on data that had been processed incorrectly.

Dr. Roger Pielke of the University of Colorado also deserves credit because he was the one who encouraged me to pursue the www.surfacestations.org project due to his broad work on land use change and its affect on regional and local climate.

Subject: Questions on correction to flaw in NASA program

From: mario@cseindia.org

Date: Tue, 11 Sep 2007 11:16:23 +0530

To: James.E.Hansen@nasa.gov, [redacted]@gmail.com

Dear Dr. Hansen,

I am with the Centre for Science and Environment (CSE), New Delhi, India and writing to you in regards to the news about the recently discovered flaw in NASA's program that computes the global surface temperature. The story is for CSE's fortnightly magazine, Down To Earth.

As part of the background reading for the story, I read through your comments and posts, 'The Real Deal: Usufruct & the Gorilla' in particular. There were some questions that came up, and I request your comments on these.

(1) This is not no relevant but for the record, when did Steve McIntyre contact GISS/NASA regarding the flaw?

(2) Is there an official statement or news release by GISS about the correction that could be quoted?

(3) I do realize that the ranking of warmest years in the U.S. is not so relevant, more so at the global scale. But for purposes of this story is there a table of the rankings prior and after the correction.

(4) From what I understand the correction only affected U.S. temperatures only in 2000 and later. But your colleague Dr. Schmidt said earlier years were affected albeit only a minor change. He said it was due to adjustments made for rural vs. urban trends. His post I'm referring to is:

{<http://www.realclimate.org/index.php/archives/2007/08/1934-and-all-that/> }
}<http://www.realclimate.org/index.php/archives/2007/08/1934-and-all-that/>

(5) Where could I find high resolution images of Figures 1, 2 and 3 in your post 'The Real Deal: Usufruct & the Gorilla.'

Your post explained the scientific arguments quite well and I haven't asked questions on those. However, I request your permission to use material from your posts for the story. Thanking you,

Subject: GISS Raw Data

From: "Steve McIntyre" <stephen.mcintyre@utoronto.ca>

Date: Sat, 4 Aug 2007 17:28:44 -0400

To: "James E. Hansen" <jhansen@giss.nasa.gov>, <rruedy@giss.nasa.gov>

Dear Sirs,

In your calculation of the GISS "raw" version of USHCN series, it appears to me that, for series after January 2000, you use the USHCN raw version whereas in the immediately prior period you used USHCN time-of-observation or adjusted version. In some cases, this introduces a seemingly unjustified step in January 2000.

I am unaware of any mention of this change in procedure in any published methodological descriptions and am puzzled as to its rationale. Can you clarify this for me?

In addition, could you provide me with any documentation (additional to already published material) providing information on the calculation of GISS raw and adjusted series from USHCN versions, including relevant source code. Thank you for your attention, Stephen McIntyre

Dear Dr Ruedy,

Thank you for this information and for the courteous acknowledgement at your website. I can now see where your post-2000 data comes from, but I remain unable to identify a digital source for your data prior to 2000 from available information. I have compared GISS raw to all the archived USHCN versions and have been unable to find a match for US data. In some cases, the differences are substantial.

Can you provide me with (1) a URL from which the U.S. data prior to 2000 (in the version that you used) can be downloaded. (2) If this is no longer possible due to the passage of time, could you please provide me with a copy of the data that you used (or upload it to an area of your FTP site) and also provide its provenance and date of acquisition? Obviously mere print citations are inadequate for this purpose.

I would like to assess the impact of these modifications on the US and global averages for myself. I would appreciate a copy of the source code used for these calculations.

Regards, Steve McIntyre

Subject: Re: GISS Raw Data

Dear Sir,

As to the question about documentation, the basic "GISS Surface Temperature Analysis" page starts with a "Background" section whose first paragraph contains the sentence: "Input data for the analysis ,..., is the unadjusted data of GHCN, except that the USHCN station records were replaced by a later corrected version". A similar statement appears in the "Abstract" and the "Introduction" section of our 2001 paper (JGR Vol 106, pg 23,947-23,948). The Introduction explains the above statement in more detail.

In 2000, USHCN provided us with a file with corrections not contained in the GHCN data. Unlike the GHCN data, that product is not kept current on a regular basis. Hence we used (as you noticed) the GHCN data to extend those data in our further updates (2000-present).

I agree with you that this simple procedure creates an artificial step if some new corrections were applied to the newest data, rather than bringing the older data in sync with the latest measurements - as I naively assumed. Comparing the 1999 data in both data sets showed that in about half the cases where the 1999 data were changed, the GHCN data were higher than the USHCN data and in the other half it was the other

way round with the plus-corrections slightly outweighing the minus-corrections.

Although trying to eliminate those steps should have little impact on the US temperature trend (much less the global trend), it seems a good idea to do so and I'd like to thank you for bringing this oversight to our attention.

When we did our monthly update this morning, an offset based on the last 10 years of overlap in the two data sets was applied and our on-line documentation was changed correspondingly with an acknowledgment of your contribution. This change and its effect will be noted in our next paper on temperature analysis and in our end-of-year temperature summary.

The effect on global means and all our tables was less than 0.01 C. In the display most sensitive to that change - the US-graph of annual means - the anomalies decreased by about 0.15 C in the years 2000-2006.

Respectfully,

Reto A Ruedy

To: "James E. Hansen" <jhansen@giss.nasa.gov>

CC: <rruedy@giss.nasa.gov>

Dear Drs Hansen and Ruedy,

I am unable to replicate how you combined data sets at Kalakan, Siberia (as an example, but this applies to other stations,)

Prior to 1987, there are two versions of this series, the values of which are identical for most periods. Nevertheless, the combined version is 0.1 deg C lower than these values.

Can you provide an explanation for this? Thank you for your attention.

Yours truly, Stephen McIntyre

PS. I would appreciate a copy of the source code that you use for station adjustments as the verbal descriptions in Hansen et al 1999, 2001 are insufficient to replicate results such as the one cited above or the change in versions previously noted,

Subject: Quarterly Averages

From: "Steve McIntyre" <stephen.mcintyre@utoronto.ca>

Date: Wed, 5 Sep 2007 11:49:36 -0400

To: "James E. Hansen" <jhansen@giss.nasa.gov>, <rruedy@giss.nasa.gov>

Dear Sirs,

In the NASA GISS dset=0 calculations, you calculate quarterly averages for periods where only 2 months are present. I have been unable to locate a description of the procedure used for this calculation in Hansen and Lebedeff 1987, Hansen et al 1999 or Hansen et al 2001. Can you please direct me to a publication in which this step of your calculation is described or alternatively provide me with an explanation. Thank you for your attention.

To: "James E. Hansen" <jhansen@giss.nasa.gov>

CC: <rruedy@giss.nasa.gov>

Dear Sirs, I notice that you've changed the historical data for some US stations since Sep 7, 2007. In particular, I noticed that temperatures for Detroit Lakes MN in the early part of the century were reduced by nearly 0.5 deg C. These changes are subsequent to your changes in August 2007 for the changing versions. To my knowledge, there is no explanation for this most recent change and I was wondering what the reason is.

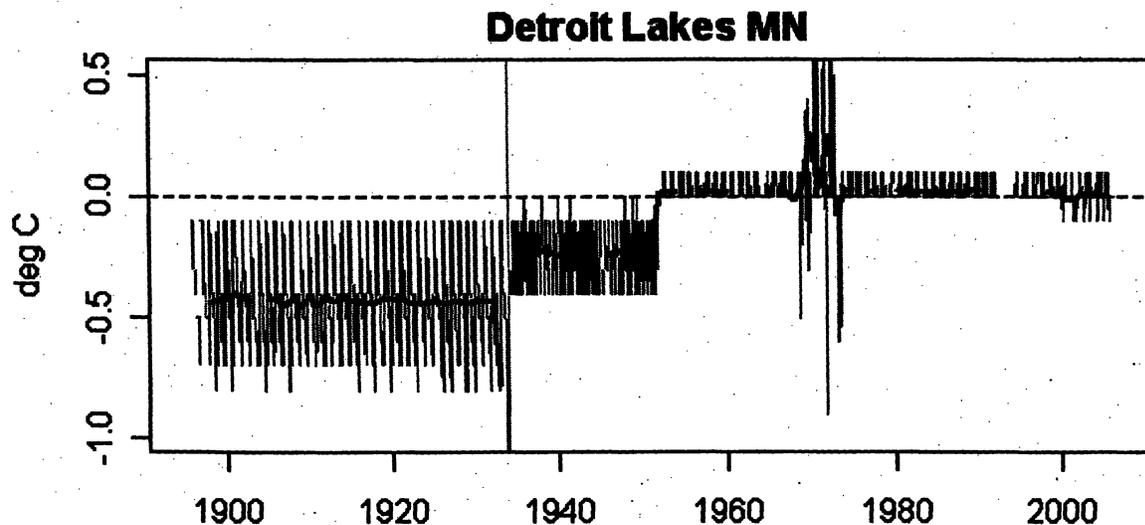

Figure 1. Difference between Sep 10, 2007 version of Detroit Lakes MN and Aug 25, 2007 version.

Thank you for your attention.

Regards,

Steve McIntyre

To: <rruedy@giss.nasa.gov>, "James E. Hansen" <jhansen@giss.nasa.gov>

Dear Sirs,

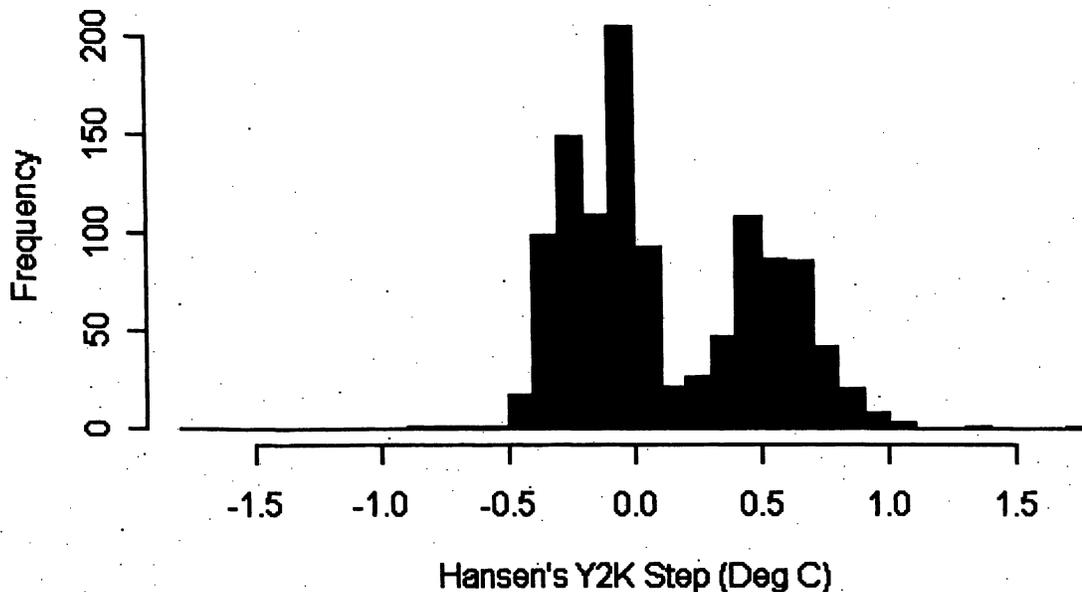

I see that you have decided to report the change in methodology as requested in my previous email. While you should have reported the change in methodology when it was made, it is better late than never.

In your new webpage, you state: " This August 2007 change received international attention via discussions on various blogs and repetition by some other media, with no graphs provided to show the magnitude of the effect." This is incorrect and I request that you correct this statement. On Aug 6, 2007, at Climate Audit, <http://www.climateaudit.org/?p=1868> , the two graphs below were provided to estimate the magnitude of the effect. The first graph shown below estimated the impact on the U.S. temperature history at a little more than 0.15 deg C. Despite having no access to your source code, this proved to be an accurate estimate.

GISS Raw minus USHCN Adj(Unlit)

The next graph shown below shows the distribution of changes over the 1221 U.S. stations, which are very substantial in individual cases. Despite your professed concern for illustrating the impact of changes, you did not yourself provide any graph to show the magnitude of the changes on individual stations, nor did you even provide explicit notice on your webpage that any changes had been made.

Would you please correct the incorrect information on your webpage. This request is made pursuant to the Data Quality Act.

Yours truly,

Stephen McIntyre

Dear Sir,

As indicated in the description of our input files, we switched from the old year 2000 version of USHCN to the current version. The differences you noticed reflect corrections that were made by USHCN within the last six years.

Dear Sirs,

Your revised webpage <http://data.giss.nasa.gov/gistemp/> contains the following incorrect statement: "This August 2007 change received international attention via discussions on various blogs and repetition by some other media, with no graphs provided to show the relevance of the effect."

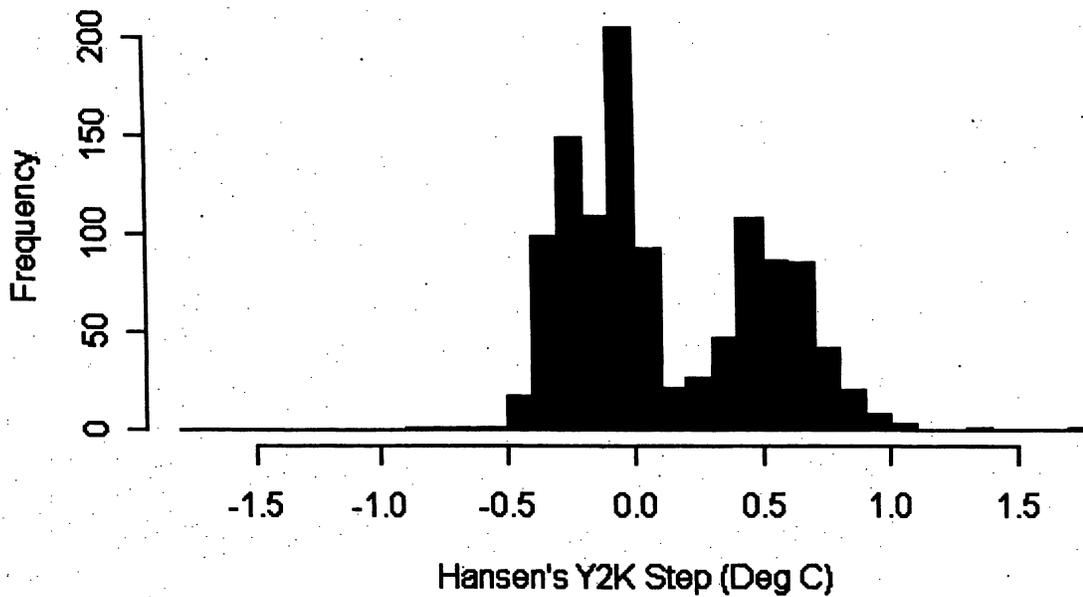

This is incorrect and I request that you correct this statement. As I advised you previously, on Aug 6, 2007, at Climate Audit, <http://www.climateaudit.org/?p=1868>, the two graphs below showed the relevance of the effect to U.S. temperature history and to U.S. stations.

The first graph shown below showed that the error was relevant to U.S. temperature history - a topic specifically considered in Hansen et al 2001.

GISS Raw minus USHCN Adj(Unlt)

The NASA website provides individual station histories, as well as U.S. and global estimates. The graph below showed the error was relevant to individual U.S. station histories.

The claim that "no graphs provided to show the relevance of the effect" remains incorrect. Once again, please correct the false statement on the NASA webpage <http://data.giss.nasa.gov/gistemp/> . This request is made under the Data Quality Act.

Yours truly,

Steve McIntyre

Dear Sir,

Thanks for bringing to our attention that the term "magnitude of effect" might be interpreted as "size" rather than "relevance", our obvious intent. We clarified our formulation correspondingly.

Subject: US temperature correction graphic and file

From: :berkeley.edu>

Date: Sun, 12 Aug 2007 04:56:49 -0700

To: "Gavin Schmidt" <gschmidt@giss.nasa.gov>, "Stephen McIntyre" <smcintyre @ ca>,
@itworks.com>, "James Hansen"
<jhansen@giss.nasa.gov>

In light of the recent fuss over the significance of the correction to the United States temperature record, I tracked down a copy of the data as it existed on August 1st (from MSN's search engine cache) and made a direct comparison (something that was largely lacking in much of the coverage of this issue).

I am distributing the comparison numbers and a graphic made from them to many of the principle commentators on this issue. Feel free to use and redistribute this at will, though I would appreciate an acknowledgment if you do so.

GISTEMP USA Temperature Correction

Subject: revisions to annual temps

From: Andrew Revkin <anrevk@nytimes.com>

Date: Thu, 09 Aug 2007 14:28:02 -0400

To: jhansen@giss.nasa.gov, gschmidt@giss.nasa.gov

hi,

you probably noticed the mcintyre et al depiction of GISS annual temp estimates for US over time.

were the revisions published yet, or are they updated in databases alone?

also, are you doing same for global mean temp or is this specific issue related to US?

thanks.

on this front, i'm mainly intrsted in global mean temp trends in any case.,

just need to keep track.

in the meantime, more melting up north>

At 11:34 PM 8/9/2007, James Hansen wrote:

Hi Andy,

This seems to be a tempest inside somebody's teapot dome. One of the changes that we made in our analysis in 2001 was to include improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations ARE in the GHCN record, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in the records at those stations, some up, some down.

The net effect averaged over the U.S. was an error of about 0.15C or less in the post-2000 years, well within the uncertainty bar that we give. The effect on the global mean was of the order of a thousands of a degree, i.e., entirely negligible.

It is unclear why anyone would try to make something out of this, perhaps a light not on upstairs? Or perhaps this is coming from one of the old contrarians? They can't seem to get over the fact that the real world has proven them to be full of malarkey! You would think that they would be ready to crawl under a rock by now!

Jim

(Reto, please correct if there is anything in the above that is not right.)

hey jim,

given that quite a few folks (gore and some enviros particularly) have often used the USA temp trends in arguments for action (string of record years) it's hard for me to ignore the reanalysis of those annual temps -- even though my own focus remains global mean temp.

essentially, should people always have paid less attention to US (48 state) trend as a meaningful signal of AGW?
(now that all those earlier warm years intrude, it certainly makes the case that regional data can be a red herring)

happy to discuss briefly by phone.
or til 6 p.m. or so

st question (promise)

Subject: last question (promise)

From: Andrew Revkin <anrevk@nytimes.com>

Date: Fri, 24 Aug 2007 09:34:29 -0400

To: gschmidt@giss.nasa.gov, jhansen@giss.nasa.gov

one point McIntyre makes that has some seeming merit is that much of the misinterpretation and flaming over this could have been avoided if GISS had done the classic public-relations management move of getting out front on this instead of being reactive.

do you think you could have handled this better?

(or is he playing both sides by doing 'leaderboard' and then trying to be serious constructive auditor?)

off record>

i never doubted the answer, but had to ask.
the spinup in blogosphere these days is instantaneous.

At 10:14 AM 8/24/2007, Gavin Schmidt wrote:

Frankly that's c**p. None of the echo chambers that took this bothered to check anything with anybody (even McIntyre) before getting all hot and bothered (including your paper's own 'Opinionater' it should be pointed out). The idea that any actions by NASA would have made a difference is laughable.

The error was corrected within 2 days and the notification made online and in an email. How does McIntyre think it could have been dealt with faster? Getting a press release put together requires weeks to get approval from HQ which would only have slowed the response. If we'd taken the time to do that, the accusation would have been of cover-up.

This is just more spin.

Reto,

is there a simple way to determine which shifts are NOT statistically significant?

in graphic we're doing, i'd love to be able to indicate that (by shading or label or the like)

At 12:53 PM 8/24/2007, Reto Ruedy wrote:

Dear Mr.Revkin,

Below are the data you requested. We really should round (as some other groups do) to the nearest tenth of a degree rather than showing 2 digits.

I tried to answer your question whether GISS ever showed a US table with 1934 warmer in the US than 1998 in an email to Jim. He found it confusing, so here is another attempt to answer it:

the answer is "yes", all our publications and all previous tables had it that way, the table we put on our web on Jan 8, 2007 seems to have been the lone exception.

Hope that is clearer.

Sincerely,

Reto

thanks reto.
this is helpful.
the story (running tonite/sunday) stresses the importance of trend over year-to-year.

At 01:14 PM 8/25/2007, you wrote:

Andrew,

I'd like to add a few notes to yesterday's response:

The estimate $+0.1C$ ($+0.2F$) tries to account for gaps in spatial coverage and missing or erroneous reports as well as, for longer time periods, changes in instrumentation or even station location and reporting procedures (how to compute the reported daily mean).

Given that the purpose of our effort is to compute long term trends, a simpler and more meaningful measure for the statistical significance is the interannual variability of the US means; its standard deviation is $0.8F$ (after subtracting the small linear trend). The corresponding number for the global means is $0.3F$.

To be remarkable, an observed change has to be a multiple of that standard deviation; compared to that, the errors caused by "bad" stations, urban heat island effect, etc. are of little importance.

Thanks. That becomes clearer. I think that the suggestion you have for fixing it is a better idea than what is being done now, though possibly it might make more sense to correct the later GHCN data rather than the earlier USHCN numbers (that doesn't make a difference to the trend of course).

Gavin

Quoting Reto Ruedy <rruedy@giss.nasa.gov>:

Gavin,

In 2000, USHCN provided us with a product in which the US data were adjusted for changes in procedure/instrumentation to get a consistent time record. According to the description on their current website, 1999 was their last comprehensive update of those data. Unlike the GHCN data, the USHCN data are not routinely kept up-to-date (at this point they seem to end in 2002).

Under the assumption that the adjustments made the older data consistent with future data, we are replacing the US part of the GHCN data up to 1999 by the USHCN data that we got in 2000, thereby eliminating some known systematic biases in the early part of the US records.

However, that assumption may not have been correct. I compared the 1999 data in GHCN and USHCN. Indeed, in 490 of the 1057 stations the USHCN data were up to 1C colder than the corresponding GHCN data, in 77 stations the data were the same, and in the remaining 490 stations the USHCN data were warmer than the GHCN data. The differences averaged out to 0.1 C, i.e. we may have introduced a +0.1C jump in 2000 over the US by our procedure.

A more careful method would have been to compare the last few years of the USHCN data and the corresponding years of the GHCN data and adjust the USHCN data to fit the GHCN data. I'll add this procedure as an alternate to see what effect it would have.

I would suggest being more specific about what was assumed and what you will do now. The stats you had for the number of stations which had positive and negative offsets would be appropriate. You also might want to thank him for bringing this to our attention. The first because he'll ask you anyway or work it out himself, the second since it doesn't hurt to be gracious.

Jim,

I've started to prepare a response to the email below. Steve is the person who appointed himself the auditor of all web sites and organizations that have to do with global warming in order to debunk this "hoax". He is maintaining a blog - a website called climate.audit.org, a site containing among justified concerns (caveats that we stress in all our papers) obvious fabrications and vicious attacks.

I'll send you my suggestion for a response before mailing anything to Steve.

Our simple combination of GHCN and USHCN data was based on the assumption that the correction made the older data consistent with the then current data. Unfortunately, that is not the case and an attempt to compute an offset based on the common years within say the 1990-1999 period would have been more appropriate.

I am re-processing our current data with that modification and wait with finishing my response until we can look at the changes caused by it. I expect only a minor effect since the offsets average out to almost 0 over all USHCN stations.

On Sat, 2007-08-04 at 17:28 -0400, Steve McIntyre wrote:

Dear Sirs,

In your calculation of the GISS "raw" version of USHCN series, it appears to me that, for series after January 2000, you use the USHCN raw version whereas in the immediately prior period you used USHCN time-of-observation or adjusted version. In some cases, this introduces a seemingly unjustified step in January 2000.

I am unaware of any mention of this change in procedure in any

published methodological descriptions and am puzzled as to its rationale. Can you clarify this for me?

In addition, could you provide me with any documentation (additional to already published material) providing information on the calculation of GISS raw and adjusted series from USHCN versions, including relevant source code. Thank you for your attention, Stephen McIntyre

I would not engage further than simply dealing with the points at hand - it's just going to further the issue. Thus I would suggest the following text alone (a couple of minor edits and one new line):

=====
The basic "GISS Surface Temperature Analysis" page starts with a "Background" section whose first paragraph contains the sentence: "Input data for the analysis , . . . , is the unadjusted data of GHCN, except that the USHCN station records were replaced by a later corrected version". A similar statement appears in the "Abstract" and the "Introduction" section of our 2001 paper (JGR Vol 106, pg 23,947-23,948). The Introduction explains the above statement in more detail.

When we originally got the USHCN data, they ended in 1999 and as far as I know, no major corrections were implemented after that time. Unlike the GHCN data, the USHCN data is not a product that is kept current on a regular basis. Hence we used (as you noticed) the GHCN data to extend the USHCN data.

I agree with you that this simple procedure creates an artificial step in those cases where the correction was applied to the newest data, rather than bringing the older data in sync with the latest measurements - which would seem the natural way to go. Comparing the 1999 data in both data sets showed that in about half the cases where the 1999 data were changed, the GHCN data were higher than the USHCN data and in the other half it was the other way round.

Eliminating those artificial steps should have little impact even on the US temperature trend (much less the global trend), but it is a good idea to do so and I'd like to thank you for bringing this to our attention.

Starting with our next update (sometime later this week) an offset based on the last 10 years of overlap in the two data sets will be applied and our on-line documentation will be augmented correspondingly.

I tested the modification with the data now on display: The table data (section 3 on the basic temperature site) differed occasionally by a 1 in the last digit (0.01 C). In the display most sensitive to that change - the US-graph of annual means - the warming decreased by about 0.15 C in the years 2000-2006.

You should perhaps note that your post 'Hansen's Y2K error' should really be titled Reto's Y2K error.

Respectfully,

etc...

I was going to reply thusly, but let me know if you'd rather I left it to you.

Gavin

Andy, this hasn't got much to do with me, but briefly, the issue was as follows. USHCN is a dataset just for the US which has included a number of appropriate corrections to the individual stations based on known site moves and changes in when the data was taken (there has been a shift towards taking data in the morning rather than in the afternoon over the decades). This data is not updated that frequently.

The main source of data is GHCN which is a global product, but that does not take into account the USHCN corrections.

The error was made in assuming that recent values of the GHCN and USHCN were the same. It turns out they weren't and so when the USHCN-corrected stations were extended to the present day using GHCN, there were a number of small jumps (of both sign) in the data. The correction that was put in was then to re-align the GHCN and USHCN data using the 1990-1999 data. This made approximately 0.15 deg C difference in the 2000-2006 period for the US mean, but it is negligible in the global mean. The data were reprocessed and the online values now incorporate that fix.

Given the nature of the error, this is purely a US issue (USHCN doesn't apply to the global data) , and as far as I'm aware, no further revisions related to this issue are likely to be forthcoming.

Gavin

One final quibble. In Fig A2, we now have the 5 year mean value for 2005 - which implies that 2007 data is being used in the calculation. But since 2007 isn't complete, that number will change by the end of the year. It might be cleaner not to calculate the that last value since it uses information that isn't seen (yet) in the annual average numbers.

Gavin

Quoting Reto Ruedy <rruedy@giss.nasa.gov>:

Makiko,

As you pointed out to me, if I keep 4 decimal places rather than 3, rounding to 2 digits will no longer be different than rounding directly to 2 digits (and I still have the 3rd digit if needed). So I will use 4 digits for internal purposes in the future.

Reto

On Sun, 2007-08-12 at 18:53 -0400, Makiko Sato wrote:

OK, I updated all versions of Fig.A and Fig.A2 with newest data with 3 digits after decimal, and manually typed in the table numbers to match Reto's tables. Since I did manually, there may be some mistakes. If you find some, please let me know.

Reto and Rob Schmunk have the details. He was using a robot to automatically download pages that robots weren't allowed to (because of the server demands of interactive scripts) and Rob blocked the IP. After a couple of emails back and forth, he was allowed to continue on weekends/evenings. The idea that this was anything personally directed at McIntyre or to prevent examination of the data is simply bogus.

Subject: McIntyre Interview

Hi, Leslie.

I've attached the complete version of the interview, but this is the part I was looking for comment on. Basically, I'd just like to know if this is true and explanation of what really went on here.

Thanks!!!

Here it is:

McIntyre: I wrote to NASA in May and asked them for the source code for the

adjustment software that they used to fix these stations and they refused to provide it. So I got interested in sort of looking at comparing the version of the temperature history of individual stations that NASA had against original data. I noticed that in some cases there was a very sharp jump in the differences between these two versions. The NASA version took a step in January 2000 relative to the original data. So, I then collected the data for both the NASA versions and the original data for all 1200 stages in the US historical network.

This led to a bit of fight with NASA in May because as I started downloading the data in sequence they cut off my access to the data.

Q. Meaning, your computer?
They blocked my IP address.

Q. Why were they so opposed?

Well, first of all they probably werent used to, they dont have a very efficient distribution of the data so I ended up scraping the data off various web pages and I had written a computer program to do that. So, I was repetitively downloading data. Anyway, even after I was blocked and I explained myself they still didnt want to let me have access to the data. They just said go look at the original data. And I said no, I want to see the data you used. I know what the original data looks like. I want to see the data that you used. But one of the nice things about having a blog that gets a million and half hits a month is that I then was able to publicize this block in real-time and they very quickly withdrew their position and allowed me to have access.

<x-flowed>

Reto and Rob Schmunk have the details. He was using a robot to automatically download pages that robots weren't allowed to (because of the server demands of interactive scripts) and Rob blocked the IP. After a couple of emails back and forth, he was allowed to continue on weekends/evenings. The idea that this was anything personally directed at McIntyre or to prevent examination of the data is simply bogus.

Hi to all:

Dr. McIntyre gave an interview to an organization called TownHall.com in which he alleges that NASA blocked his IP address and that because of 1.5 million hits/month on his website, NASA retreated from its position. She wants to know if this is an accurate retelling of what occurred?

The attachment is her ENTIRE 4 page interview which details in greater length the timeline and interactions with GISS....

Thanks.

Leslie

Subject: McIntyre Interview
```

Hi, Leslie.

I've attached the complete version of the interview, but this is the part I was looking for comment on. Basically, I'd just like to know if this is true and explanation of what really went on here.

Thanks!!!

Here it is:

McIntyre: I wrote to NASA in May and asked them for the source code for the adjustment software that they used to fix these stations and they refused to provide it. So I got interested in sort of looking at comparing the version of the temperature history of individual stations that NASA had against original data. I noticed that in some cases there was a very sharp jump in the differences between these two versions. The NASA version took a step in January 2000 relative to the original data. So, I then collected the data for both the NASA versions and the original data for all 1200 stages in the US historical network.

This led to a bit of fight with NASA in May because as I started downloading the data in sequence they cut off my access to the data.

Q. Meaning, your computer?
They blocked my IP address.

Q. Why were they so opposed?

Well, first of all they probably werent used to, they dont have a very efficient distribution of the data so I ended up scraping the data off various web pages and I had written a computer program to do that. So, I was repetitively downloading data. Anyway, even after I was blocked and I explained myself they still didnt want to let me have access to the data. They just said go look at the original data. And I said no, I want to see the data you used. I know what the original data looks like. I want to see the data that you used. But one of the nice things about having a blog that gets a million and half hits a month is that I then was able to publicize this block in real-time and they very quickly withdrew their position and allowed me to have access.

mcintyre_isp_08-15-07.doc

Content-Type: application/msword
Content-Encoding: base64

On May 16, 2007, an IP address attached to an address in the domain of Rogers Communications, a Canadian phone company and ISP made 16,000 attempts in several hours to scrape GISTEMP station data. The webmaster had noted that this large volume was dramatically slowing access to the site and data by other users. He identified that this activity was from an "automated" agent which, in rough parlance, is usually called a "robot". That address was blocked by the GISS webmaster as it violated rules from using web robots to access off-limits directories, particularly those with interactive scripts. The webmaster had no idea of the identity of the user until Dr. McIntyre emailed the webmaster seeking clarification on why he was unable to ~~log in~~ access the site. It should be noted that this was routine; denials of service have been made in the past under similar circumstances to other users as well.

Dr. McIntyre was then advised of the reason for his service denial and advised to contact the GISTEMP research group to explain data needs. On the 17th, Dr. McIntyre again inquired about his access and was again advised to contact the GISTEMP group. Dr. Reto Ruedy of the GISTEMP group contacted Dr. McIntyre to discuss his requests. Data on the GISS site is organized for users to view individual stations rather than for massive downloads and in an attempt to assist him, he was directed to NOAA's Global Historical Climatology Network (GHCN).

~~Some data providers insist that NASA GISS does not pass on their data and, as such, we are asked to refer requests to them, since they want to keep control of their own data. Dr. McIntyre's first request for "our code" came in the same email in which he thanked GISS for giving him full access to data. His request was so general that GISS had no idea what code he was talking about. Only after consulting his blog site was it learned that he was under the false impression that GISS has secret software that can "fix" faulty data. As NASA GISS does not have any such software, we were unable to honor his particular request.~~

Shortly after that email exchange, Dr. McIntyre was advised that he could again begin downloading provided that he accepted generally accepted protocols, i.e. doing so at times so as to not adversely affect other users (late nights, weekends, etc.). He replied "thank you for this. I will observe this condition."

the issue is here that you are dealing with a hostile interviewer. In such circumstances, it is much better simply to point out clear errors. If you open up another front they will dive on that instead and abandon all the previous positions (since they are not sincere in any case).

It does however highlight the rhetorical power of saying that the code is secret and things are being kept from the public. It may still be worth putting up a clean version of the adjustment program on the website in order to have something to point to in such cases.

gavin

On Thu, 2007-08-16 at 18:08, Reto Ruedy wrote:

Gavin,

So you don't think it is worth to point out that the whole first part of the interview section below is a total fabrication, and his first request for source code came with the "thank you" note mentioned at the end of the response, still May 17. Also, his reasons for our "reluctance" is wild speculation that is light years away from reality.

On second thought, it's not worth going into these details, especially in a case where the interviewer is more likely to believe Steve than us.

So, I'm fine with the edits.

I didn't suggest using their urban adjustment, but that the most up-to-date USHCN data may have more in the way of documented station adjustments and more data earlier on. The FILIN data do not include their urban adjustment as far as I can tell. I get the impression from the USHCN web site that you should be able to extract just the TOBS corrected data without the FILIN.

The point is to make sure that the difference between the earlier USHCN data set we were using and the latest version does not make a significant difference to the results. Since any independent replication of the GISS procedure will use the currently available data set (not the one we are using), we should probably be ahead of the game in understanding what impact it has.

As is usual in these cases, the smarter of the court jesters have already stopped talking about 1934 and are now pushing the transparency 'meme'. That has a lot more resonance....

Jim,

Gavin suggested some time ago that we should do the analysis with the current USHCN.

I downloaded the "FILIN" USHCN data; the filled-in numbers are marked.
So I can use or ignore them. I have to write a program anyway to reformat this file to the format used by GHCN. This includes the easy conversion from F to C, but they also use a different set of ID-numbers to characterize the station. So first, I'll have to construct and check a conversion table to identify the stations properly.

Frankly that's c**p. None of the echo chambers that took this bothered to check anything with anybody (even McIntyre) before getting all hot and bothered (including your paper's own 'Opinionater' it should be pointed out). The idea that any actions by NASA would have made a difference is laughable.

The error was corrected within 2 days and the notification made online and in an email. How does McIntyre think it could have been dealt with faster? Getting a press release put together requires weeks to get approval from HQ which would only have slowed the response. If we'd taken the time to do that, the accusation would have been of cover-up.

This is just more spin.

Hi Jim,

Over the weekend, I used the newest version of the USHCN data to redo our analysis; I did it twice, with and without the data USHCN filled in.

No surprises; between 1920 and 2005 the change in the US ann. means was less than 0.02 C, the largest difference was in the 1880's (<0.16 C). With the new data, the US trend will be slightly higher.

The only interesting thing was, that my first attempt to process these data failed. It turned out that our program could not handle the attempt to remove data that were not present.

All went fine when I took the US stations off our list of manual corrections.

It seems that all our manual deletions of parts of USHCN data were also either deleted or modified in the new USHCN data. Their more rigorous purging of odd-looking beginnings of station records seems to be the main reason for the changes.

I suggest, we switch to the new USHCN data for future updates. It does not matter much to keep or not to keep USHCN fillers; not keeping them is a little more in line of what we did so far.

that's one less thing to worry about!

I wouldn't recommend changing the format - any such change is bound to be interpreted as an attempt to spin the numbers.

I take it that the 2006, 2007 numbers from GHCN are offset so that there is no discontinuity when going from USHCN to GHCN as you did for the post 2000 numbers in the last analysis?

If and when Jim decides to adopt this, I also recommend that we have a specific page outlining the change and the differences it makes so that there is no accusation that we're quietly fiddling the numbers.

thanks,

Gavin

WSJ op-ed's are completely separate from the journalism side. They are also insane.

Gavin

On Thu, 2007-08-30 at 12:40, Reto Ruedy wrote:

Is this an editorial ? If so, they disregarded their Aug 16 article written by their scientific consultant Keith Winstein.

They also repeat Steve's inane comparison of a warming of .21 C/86 years (or .21 C for the 1920-2006 period) to the .15 C temperature correction - the 2 quantities don't even have the same units (like comparing 2 miles to 2 miles/hour). Based on the corrected numbers, the 1920-2006 warming now agrees with the reported .21 C (that number probably came from NOAA). Based on the uncorrected data it would have been .27 C for that period - but nobody here ever computed or cared for it, much less publicized it.

Reto

PS. I'd rather not talk to any journalist at this point. Did Gavin or Jim respond ?

Hi Jim: Understand you have had a busy summer. I had a few issues I would like to touch base with you on.

(1) Concerns telephone call with Ralph Cicerone concerning Steve McIntyre, data request and tactics.

(2) Would like to get you to Ohio State in 2008 to give the Bownocker Lectures. We are pretty open on times. The lectures are scheduled on Thursday but any Thursday between Feb. 21 and March 6th or between March 27 and May 8th would work. There are two lectures: one at 4:00 PM which is more technical and a public lecture at 8:00 PM. These would be in our new School of Earth Sciences. All expenses would be paid and there is a \$1000.00 honorarium. More important, I know how busy you are and the toll that lectures take.

Hope you can fit us in your busy schedule next spring. Appreciate very much what you do in getting the message to the public. Please let me know if you can fit this into your schedule.

You can telephone my direct line:

Best wishes,

Lonnie

All -

Can any of you help me find the place on the NASA site to which he's referring? I need to get back to a reporter, so I'd love any help I can get. Our HQ scientists aren't familiar with any change. Thanks!
Tabatha

Jack,

Per our discussion, please review the following statement. Once I hear from you, I'll send it to our web people.

ttt

Researchers at NASA's Goddard Institute for Space Studies in New York recently revised information on their global temperature record based on corrected data. The computer modeling program that generated the temperature record was produced with the assumption that data from monitoring stations would be adjusted to account for changes such as the time of day at which measurements were made. However, the adjusted data were not always readily available and the program used data from monitoring stations that had not been adjusted. The result was a discontinuity in temperature variance in 2000. The researchers have corrected the computer program and posted their revised data. More information is available here: [\(LINK TO GISS SITE\)](#).

MERIDIAN MAGAZINE

All in a Good Cause

By Orson Scott Card

Editor's note: This article first appeared in The Rhinoceros Times of Greensboro, North Carolina, and is used here by permission.

Here's a story you haven't heard, and you should have.

An intelligence source, working for a government agency. He's not a spy, he's an analyst. He uses computers to crunch numbers and at the end of his work, out pops the truth that was hiding in the original data. Let's call him "Mann."

The trouble with Mann is, he has an ideology. He knows what he wants his results to be. And the original numbers aren't giving him that data. So the agency he works for won't be able to persuade people to fight the war he wants to fight.

Well, that's not acceptable.

Cooking the Figures

He starts with his software. There are certain procedures that are normal and accepted in his line of work. But if he makes just one little mistake, his program does a weird little recursion and if there's any data at all that shows the pattern he wants it to show, it will be magnified 139 times, so it far overshadows all the other data.

He can run it on random numbers and it gives him the shape he wants. Unfortunately, the real-world numbers aren't random — they have a very different shape. All the numbers. Even his jimmied program won't give the results he wants.

All he needs is any data shaped the right way. And so he looks a little farther, and ... here it is. It looks, on the surface, like all the other data that he's been working with. Other researchers working in his field, just glancing at it, will assume it is, too.

But it isn't. Because the source that gathered this batch of data had some other key information that takes it all away. The numbers don't mean what they normally mean. In fact, this number set is absolutely false.

If you use these numbers along with all the other data, however, the clever little program will pick them up, magnify them radically, and voilà! The final report shows exactly the shape he needs the numbers to have.

The trouble is, these numbers are supposed to be double-checked. Anybody who looks closely at his numbers

and at his program will see what he's done. It's not hard to find, if you have the original data sets and can examine the program. He will be exposed as a fraud. It will do his cause more harm than good, if it's made public.

But he's not afraid. He knows how this works.

He doesn't show the program or the lists of his data sources to anybody.

Second, he is given a big boost by the fact that another researcher — we'll call him "Santer" — had his own axe to grind. He was also the author of a questionable report and got himself appointed to a position that allowed him to get to the final report before it's published, delete all statements about how "there is no way to reach a definitive conclusion," and replace them with his own conclusion, which is absolute.

And it works. Santer's report is accepted, even though it has since been proven false. Mann's report continues to be relied on, and no one questions it. The government agency issues the report which they know has been altered to fit preconceived conclusions.

Vast sums of money are expended on the basis of what he claims to have found. People's lives are put at risk.

Mann and Santer didn't do it for the money, though grants do flow in their direction.

They did it for the cause. It's a noble cause. And even though the data don't actually say what they wanted them to say — in fact, they say the opposite — they are untroubled by that. Because the government actions that are being taken are the Right Thing.

Santer and Mann are true believers. They don't need evidence. Evidence is just something you create to persuade other people.

Here's the amazing thing about Mann's original report: He's not the only researcher working in this field. In fact, it's the job of many hundreds of researchers to refuse to accept his data at face value. After all, his findings disagree with everyone else's. Before they accept his results, they have a duty to look at his software, look at his data, and try to duplicate his results.

But nobody does it. Not a soul.

Nor, when it goes public, does anyone in the press check the results — because they want him to be right, too.

Steve the Canadian Businessman

Not until a Canadian businessman — let's call him "Steve" — took a look at the stats and got curious. Now, it happens that Steve is in the mining business; he also happened to be a prize-winning math student in college. He knows how to read number sets. He knows what good analysis looks like.

He also knows what cooked figures look like. He has seen the phony projections that companies use when they're trying to swindle people. Their results are too perfect. Mann's report looks too perfect, too.

So Steve starts digging. First, he reads Mann's original report. He finds it an exercise in obscurity. From what he published, it's very, very hard to tell just what statistical methods Mann used, or even what data he operated on.

This is wrong — it's not supposed to be that way. Scientists are supposed to leave a clear path so other people can follow them up and replicate their research.

The fact that it's so obscure suggests that Mann does not want anyone checking his work.

But Mann used government grants in his research. Which means he has an obligation to disclose. Steve contacts him, asks for the information. He gets a runaround. He gets pointed to a website that does not have the information. He tries again, and again gets a runaround — in fact, Mann sends him a very rude letter saying that

he will no longer communicate with him.

Why should he? Steve isn't a legitimate researcher in that field. He's just a businessman.

But Steve is now sure there's something fishy going on, and he doesn't give up. He gets other people to help him. Finally they are pointed to a different website, where, to their surprise, they find that someone has accidentally left a copy of the FORTRAN program that was used to crunch the numbers. It wasn't supposed to be where Steve found it — which is why it hadn't been deleted.

Also, there was a little more carelessness — there is a set of data labeled "censored." Steve can't see, right away, what's significant about it, except that a score or so of data sets are left out of the censored data.

Steve looks at the program. He finds the glitch rather easily. He tries the program on random numbers and realizes that it always yields the distinctive shape that has caused all the stir.

Sorting out the data sets is much harder. He contacts a lot of people. He does what anyone checking these figures would have to do, and he realizes: If anyone had tried to check, a lot of this information would already have been put together.

He realizes: I am the first person ever to attempt to verify these astonishing, anomalous, politically hot results. Out of all the researchers in this field who had a responsibility to do "due diligence" before accepting the data, none of them has done it.

Finally he has all the original data put together. It includes more than just real numbers — it includes "extrapolated" data, which means that sometimes, where there were holes, Mann just made the numbers up and plugged them in. This is sloppy and lazy — but it's just the beginning.

What's crucial is that Steve now understands why the "censored" data sets are smaller than the ones Mann used. The full source data includes those misleading results that shouldn't have been used. But the "censored" data sets leave it out.

This means that Mann knew exactly what he was doing. This was not an accident. Mann ran the program on the data without the misleading numbers, and then he ran it with the misleading numbers. What he published was the results that made his ideological case.

Where's the Press?

This story is true.

Anybody who cares to can verify the story. In fact, one of the leading science journals was prepared to publish Steve's results. But then, before publication, they kept cutting back and cutting back on the amount of space they would let Steve's report take up in the journal.

Finally the space they were going to allot was so small that they concluded Steve could not tell his story in that number of words, and therefore they decided not to publish it at all.

Meanwhile, serious publications did publish Mann's savage response to what Steve was saying on the website where he was putting up his results for everyone to read.

Notice: Steve is making all his work transparent to the world — anyone is free to check his data.

Mann is still hiding, denying, attacking — but not providing the full information. You still have to do detective work to ferret it out.

Now, if you were a reporter — you know, those brave guys and gals who are committed, body and soul, to "the public's right to know" — wouldn't you smell a rat? Wouldn't you jump on the chance to expose such an obvious fraud?

After all, there are now governments all over the world basing their decisions on Mann's false report. Crucial decisions are being made. Schoolchildren are being terrorized with dire projections of what will happen if Mann's report is not believed and acted upon. Vast sums of money are being spent. People are treating Mann's cause as a crusade — and his fake results are the chief weapon they use to prove their case.

Where's the press? Why am I able to tell you this story in full confidence that very few who are reading it will have ever heard it before?

Because Mann doesn't report to the Bush administration. The government agency for which the result was filed was a UN agency — specifically, the Intergovernmental Panel on Climate Change.

And Mann's report is the famous "hockey stick" that "proves" that global warming not only is happening, but right now we're in the warmest climate period in the past thousand years.

Ah! You've heard of that report, haven't you! The press has been all over that one! Your kids are being taught about it in school!

You have friends who look at you like an idiot or the scum of the earth if you don't get energized by it, frightened by it, determined to act on that information. Don't you care about the future of the environment?

Why haven't you joined the cause? Why doesn't the Bush administration act to save the world from the most terrible threat imaginable?

It's like the opening of the "Talk of the Town" section of the February 12th *New Yorker*. "Except in certain benighted precincts — oil-industry-funded Web sites, the Bush White House, Michael Crichton's den — no one wastes much energy these days trying to deny global warming."

This statement is not just false, it's stupidly false. It speaks of such deep ignorance at *The New Yorker* — ignorance that they're actually proud of — that it makes one despair, for this is a magazine that once prided itself on knowing what it was talking about.

"By the time the IPCC publishes an assessment, it has been vetted by thousands of scientists," says *The New Yorker* — but we know that in fact nobody vetted the Mann paper, and nobody checked Santer except, of course, Santer — while he went ahead and removed statements of some of those "thousands of scientists" (p. 27).

In other words, whoever wrote this *New Yorker* piece did not check. He or she just spouted.

What is really being said here is, "We believe in the IPCC and anybody else who supports Global Warming. We believe it so much that we refuse to listen to anybody who says otherwise."

The only difference between this and Jim and Tammy Baker on the old PTL Club is that nobody says "Jesus." It's all faith, no science.

They're like four-year-olds putting their fingers in their ears and chanting "La la la la" until the person talking to them goes away.

The Hockey Stick Hoax should be a scandal as big as the discovery of the Piltdown Man Hoax. Bigger, really, since so much more is at stake.

But because the media are dominated by True Believers, they are doing everything they can to maintain the hoax, to keep the public from learning the truth.

What were those bad numbers Mann plugged in to get his fake results? Modern bristlecone pine tree-ring data in which recent tree rings showed the widths that would normally mean unusually warm weather.

However, these trees were located near temperature recording stations that showed lower than usual temperatures. So instead of being a sign of warmer temperatures, the tree rings are actually responding to the increased CO2 levels.

Even the heading on this bristlecone pine study clearly stated that the wider tree rings did not indicate higher temperatures. But Mann plugged them in as if they did, producing the one dataset that showed "warmer weather" (i.e., wider tree rings) in recent years, allowing the defective software to produce its hockey-stick result.

The bristlecone pine study was real science. Mann's use of it was deliberately fraudulent.

How Can We Know What's True?

All this can be checked. I didn't even change the names. "Mann" is Michael Mann; his co-writers on that hockey stick report are Raymond Bradley and Malcolm Hughes. "Steve" is Stephen McIntyre, and the writer of the report I'm working from is Ross McKittrick, who is a climate scientist. Their report is a chapter in *Shattered Consensus: The True State of Global Warming*, edited by Patrick J. Michaels.

Do you know how True Believer scientists respond to this? Just like the ignorant New Yorker writer. There's no attempt to answer any specific charge. They simply dismiss any disagreement by saying, "All the smart scientists agree that global warming is happening; anybody who denies it is just a crank, and you should ignore them."

This is exactly the kind of bias that President Bush's enemies accuse him of having during the run-up to the Iraq War. They claim that Bush and his people only believed the intelligence reports that told them what they wanted to hear, and ignored the rest, claiming that "everybody knew" things that were false.

That's not what happened with Bush (but you don't actually have to prove accusations against President Bush these days). But with the Hockey Stick Hoax it can be proved — yet the very same reporters pay no attention at all. It's "not a story."

In other words, the very people who attack Bush as a liar are actually behaving exactly as they accuse Bush of behaving.

Global Warming vs. Climate Change

If you pay close attention, you'll find that Global Warming alarmists are not actually saying "Global Warming" lately. No, nowadays it's "Climate Change." Do you know why?

Because for the past three years, global temperatures have been falling.

Oops.

The thing is, we've had twenty years since the Alarmists first raised the banner of Global Warming. They told us that "If This Goes On" by 2010 or 2020, sea levels will be rising so high that coastal cities will be flooded, famines will cover the earth, and ...

Oh, you know the list. They're still making the same predictions — they just move the dates farther back.

It's like those millenarian religious cults in the 1800s. Religious leaders would arise who would predict the Second Coming of Christ in 1838. When Christ didn't oblige them by showing up, they went back to their visions or scripture calculations or whatever they claimed and report that they miscalculated, now it was going to be 1843. Or whatever.

Here's the raw truth:

All the computer models are wrong. They have not only failed to predict the future, they can't even predict that past.

That is, when you run their software with the data from, say, the 1970s or 1980s, and project what should happen in the 1990s or 2000s, they project results that have absolutely nothing to do with the known climate data for those decades.

In other words, the models don't work. The only way to make them "work" is to take the known results and then fiddle with the software until it finally produces them. That's not how honest science is done.

Why are so many scientists so wrong?

First of all, there aren't all that many scientists. You hear about how "everybody" agrees about global warming. But who is "everybody"?

I had somebody at a conference get very angry with me for even raising a question. "I have a friend who's a climate scientist and he says that the Everglades are definitely drying up!"

But that's not the question, I said. Global warming isn't even the question. The question is, what is causing global warming or cooling or climate change? Is it human carbon dioxide emissions or something else? Your friend is studying aquifers in one specific area. In what way is he qualified to speak about global climate?

The only answer I got was the answer you always get when you challenge the roots of someone's religion — fury, dismay, and a refusal to talk about it any more.

That's what happens over and over. Who are the scientists who are qualified to speak? There aren't that many. It's the relatively few scientists who are studying paleoclimate and those who are working on contemporary data collection and collation and analysis.

And here's where it almost gets funny. Even the IPCC, which was so heavily biased in favor of Global Warming alarmism, could not get its pet scientists to agree that Global Warming in recent decades is even probably caused by human activity.

What is Driving Global Climate?

Science isn't done by consensus. It's done by rigorous testing. When a hypothesis — or a computer model — fails to correspond to the actual real-world data, you throw them out

That's what the real climate scientists are doing. They have found, in recent years, a very close correspondence between global climate and variations in the amount of radiation the Earth receives from the Sun.

The light and heat we get varies depending on the distance and position of the Earth and the amount of radiation the Sun puts out. The Earth's distance and position seem to determine the big cycles — the Ice Ages — and the Sun's variations seem to determine the smaller climate cycles.

We have historical data indicating several global warm periods. There was one during the heyday of the Roman Empire; then there was a global cooling during the Dark Ages (beginning about 600 A.D.) The Medieval Warming kicked in about 950, followed by the Little Ice Age beginning about 1300.

The Little Ice Age ended in about 1860. You'll notice that most reports on our modern Global Warming set that as their base point, and leave out all prior warmings.

But those warm periods are real, as are the cool periods. Ice core samples from various places around the world back it up, as do ocean floor samples. In fact, the predictions based on the 1500-year (approximately) solar cycle are borne out everywhere.

There's now at least as much real-world evidence supporting the solar cycle as the cause of climate variation — including all of today's climate variation — than there was for, say, tectonic plates or the asteroid-caused extinctions at the time when they were first plastered all over the media as the hottest science news of their day.

It's not that it's really a secret. The book *Unstoppable Global Warming* by Singer and Avery tells us what the media could easily have reported to us:

"On 16 November 2001, the journal *Science* published a report on elegant research, done by unimpeachable scientists, giving us the Earth's climate history for the past 32,000 years — along with our climate's linkage to the sun" (p. 8).

They quote Richard Kerr of Science:

... the climate of the northern North Atlantic has warmed and cooled nine times in the past 12,000 years in step with the waxing and waning of the sun.

And Kerr quotes glaciologist Richard Alley of Penn State:

The ... data are sufficiently convincing that [solar variability] is now the leading hypothesis to explain the roughly 1,500-year oscillation of the climate seen since the last ice age, including the Little Ice Age of the 17th century (p.8).

We're not talking about fly-by-night wackos. We're talking about leading scientists doing solid research.

And other scientists have found data that correlates closely with their findings all over the world. In other words, these solar oscillations account, completely, for the global variations.

The opposite is the case with the Global Warming alarmists. Their human-emitted carbon dioxide hypothesis is made ludicrous by the fact that most of the warming since the 1860s occurred before 1940, an era when human CO2 emissions were not significant. And we had significant global cooling between then and 1970, precisely the period when CO2 emissions were steeply rising.

CO2 really is rising, though. Any greenhouse heat effect seems to be dissipated by a newly discovered "Pacific Heat Vent." Moreover, CO2 emissions are provably involved in fertilizing vegetation wherever CO2 levels have risen.

Global Warming "Solutions"

We can't stop global warming or cooling. We simply don't have the power to do it. We can't heat up or cool down the sun; we can't jiggle the Earth in its orbit or change its position. We'd be idiots to try, even if such unimaginable powers came within our reach.

So we'll continue, as long as the human race persists, to have ice ages and warm periods, with relatively minor oscillations (like the Little Ice Age and our current warm period) in between.

In fact, what we have right now, while we are not yet as warm as the peak of the Medieval Warming (a fact that Mann and others have tried to deny or obscure), is a superb climate that is making life better for people all over the world. It's the cold periods that cause famines and population drops, and promote plagues and floods.

We should be grateful.

Instead we are being hit with dire warnings, every one of which is either false or a normal part of the Earth's history; our business should be to adapt to the unavoidable solar-caused warming, not to destroy the worldwide economy in order to prevent something that human activity is not causing.

Because the "solutions" proposed by the alarmists do not solve anything — and they admit it! The drastic proscriptions of the Kyoto Protocols, even if anybody were actually following them, would not have had any effect on Global Warming, even if it had been caused by human CO2 emissions.

Do you understand that? When Al Gore goes on and on about what we must do to save the Earth, he knows — and everybody involved with the Global Warming alarmist movement knows — that none of their drastic proposals would have the slightest effect on Global Warming even if it worked they way their fantasies say it does.

So why do they propose it? There are many personal motives, of course, but when you look at the non-solution "solutions" they propose, the pattern is clear. They are not trying to stop global warming. They are trying to punish the Western democracies for being richer than the rest of the world.

There are solutions to that problem (and I believe it is a problem), but they involve stabilizing bad governments, increasing international trade, and making unsafe parts of the world safer so they can take part in the global boom.

Not only that, but many of the programs the alarmists advocate are actually needed for completely unrelated reasons. It is a mark of our folly and blindness that we continue to be so ridiculously oil-dependent all these years after the oil embargo of 1973.

For national security, environmental, futuristic, and personal-happiness reasons we should be working hard to change our automobile centered culture into more civilized patterns that invariably make people happier wherever they are tried.

It can't be done by cutting back on automobile emissions or even by raising taxes on gasoline — especially because these changes are hardest on the poor and the marginal middle class.

But I'll write about how and why we need to cut back on our destructive love affair with that faithless mistress, the car, in another column.

What matters right here and now is that it is time for the world's scientists to apostatize from the Church of Global Warming. It is a false religion. It is based on lies, and its leading prophets know that it is because they're the ones faking the data or stretching it to ridiculous lengths to pretend that the real world hasn't already ruled against their claims.

It is time for our school systems to stop accepting the gospel of that false religion and start doing their due diligence. Our children should be taught about the demonstrable solar cycles and the whole human-caused Global Warming theory, along with the Hockey Stick Hoax, should be taught only as another example, after Piltown Man and pre-Copernican theories of planetary movement, of how science can be corrupted when ideology gets ahead of the data.

It is time for us to laugh at the ideologues who try to pretend that any criticism of Global Warming alarmism is idiotic and unscientific. They are the ones who ignore the data; they are the ones who believe on faith alone, without evidence; and, most important, they are the ones who are trying to stifle the opposition without answering it.

The Global Warming alarmists are the anti-science religion that is trying to forcibly indoctrinate and convert everyone while suppressing dissent. And the news media are their patsies, their stooges, their puppets.

Right now, let's start demanding that whenever the local newspaper or TV stations say anything about Global Warming, they back it up with actual data that takes into account the solar oscillations, the real climate history of the earth, and the facts about what CO2 actually does in the atmosphere.

It's time to stop letting them lie pass along other people's lies. It's time for the news media to stop doing cocktail party "research" and dig down into the science and get it right.

Read It for Yourself

I could not possibly array all the evidence here; you must read the books for yourself. *Unstoppable Global Warming* is a highly accessible book written for ordinary educated readers. It's the book I recommend most highly.

Shattered Consensus, on the other hand, uses the language of various disciplines of science to a degree that makes some chapters fairly difficult for untrained readers, though the key chapter I cited here, on the Hockey Stick Hoax, is quite readable and worth looking at by everybody.

S. Fred Singer and Dennis T. Avery, *Unstoppable Global Warming: Every 1,500 Years*.

Patrick J. Michaels, ed. *Shattered Consensus: The True State of Global Warming..* (See especially: Ross Mckittrick, "The Mann et al. Northern Hemisphere 'Hockey Stick' Climate Index: A Tale of Due Diligence," pp. 20-49.)

ANOTHER PALAEO-CLIMATE DISASTER MYTH IN DOUBT

Canadian scientists studying ice core records are questioning current theories about the rapid cooling of the Northern Hemisphere 8,200 years ago. Many scientists link that event with the final drainage of Lake Agassiz, a large glacial lake that once covered much of central Canada. The drainage is thought to have freshened waters in the northern Atlantic Ocean, slowing the oceanic circulation that helps distribute heat. The researchers found the lake's drainage occurred between 8,500 and 8,350 years ago and that sea-surface and deep-current conditions determined from oceanic sediment cores lack significant concurrent changes in the northern Atlantic.

–United Press International, 20 August 2007

PREDICTING climate change is a tricky business, so thank heavens for computer programmes that can take a melting ice sheet here and an El Niño effect there and turn it into a recipe for disaster. But not so fast, says Lenny Smith, a statistician at the London School of Economics who is concerned by the "naïve realism" of climate modelling. Smith singles out the British Government's UK Climate Impacts Programme and the Met Office for making detailed climate projections for regions of the UK when the global models vary widely. Policymakers "think we know more than we actually know. We need to be more open about our uncertainties", Smith says.

–The Times, 21 August 2007

Recently a friend mentioned that he was concerned about health effects from wi-fi. I pointed out that this was likely an overblown concern, fed by the media echoes of a scare mongering BBC Panorama program, and pointed him at the coverage at Ben Goldacre's blog "Bad Science" for a through takedown of the whole issue. To my surprise he came back more worried than ever. He had watched the program on the Bad Science page, but not looked very much at the damning criticism surrounding it. After all, a warning is much more salient than a critique. My friend is highly intelligent and careful about his biases, yet fell for this one.

(1) ANOTHER PALAEO-CLIMATE DISASTER MYTH IN DOUBT

United Press International, 20 August 2007
<http://www.physorg.com/news106846404.html>

Canadian scientists studying ice core records are questioning current theories about the rapid cooling of the Northern Hemisphere 8,200 years ago.

Many scientists link that event with the final drainage of Lake Agassiz, a large glacial lake that once covered much of central Canada. The drainage is thought to have freshened waters in the northern Atlantic Ocean, slowing the oceanic circulation that helps distribute heat.

Canadian scientists C. Hillaire-Marcel and Anne de Vernal of the University of Quebec and McGill University, along with David Piper of the Geological Survey of Canada, studied oceanic records downstream from Lake Agassiz's flood discharge route.

The researchers found the lake's drainage occurred between 8,500 and 8,350 years ago and that sea-surface and deep-current conditions determined from oceanic sediment cores lack significant concurrent changes in the northern Atlantic.

Instead, the scientists said the data show the 8,200-year-old cooling event was generated by several factors, including melting of North American continental glaciers and a subsequent rapid sea level rise that induced a large-scale reorganization of broad oceanic circulation patterns.

The study appears in the journal Geophysical Research Letters.

(2) LAKE AGASSIZ FINAL DRAINAGE EVENT IN THE NORTHWEST NORTH ATLANTIC

GEOPHYSICAL RESEARCH LETTERS, VOL. 34, L15601, 2007
<http://www.agu.org/pubs/crossref/2007/2007GL030396.shtml>

Lake Agassiz Final drainage event in the northwest North Atlantic

C. Hillaire-Marcel
GEOTOP, Université du Québec à Montréal, Montréal, Quebec, Canada

Anne de Vernal
GEOTOP, Université du Québec à Montréal, Montréal, Quebec, Canada

David J. W. Piper
Geological Survey of Canada-Atlantic, Dartmouth, Nova Scotia, Canada

Abstract

The 8.2 ka "climate" event recorded in Greenland ice cores is subject of debates with respect to causal linkage with a collapse of the Atlantic Meridional Overturning due to the drainage of the late-glacial lake Agassiz. Here, we present records from the NW North Atlantic, down-current the flood discharge route, showing that the 9.5-8 ka interval was marked by a succession of events. The drainage itself corresponds to a twin-layer of carbonate-rich turbidites deposited

within the calibrated 8.35-8.5 ka interval. Proxies of sea-surface and deep-current conditions do not indicate significant concomitant changes in the NW North Atlantic. The dataset, however, supports the concept that the 8.2 ka "climate" event may represent one of the manifestations of climate instability during an interval with major changes of land drainage in NE America, due to the collapse of the Laurentide Ice Sheet, subsequent fast sea level rise and large scale reorganization of the North Atlantic thermohaline circulation pattern.

Received 8 May 2007; accepted 3 July 2007; published 2 August 2007.

Keywords: NW North Atlantic; early Holocene; Lake Agassiz.

(3) OPINION: THE JURY IS STILL OUT ON GLOBAL WARMING

The best widely read daily English language paper in Europe - Ed

International Herald Tribune, 20 August 2007

<http://www.iht.com/articles/2007/08/20/opinion/edjacoby.php>

By Jeff Jacoby

If there's anything climate-change crusaders are adamant about, it is that the science of the matter is settled. That greenhouse gases emitted through human activity are causing the planet to warm dangerously, they say, is an established fact; only a charlatan would claim otherwise.

In the words of Al Gore, America's leading global warming apostle: "There's no more debate. We face a planetary emergency. . . . There is no more scientific debate among serious people who've looked at the evidence."

But as with other claims Gore has made over the years ("I took the initiative in creating the Internet"), this one doesn't mesh with reality.

Scientists and other "serious people" who question the global warming disaster narrative are not hard to find. . . . Plainly, the science isn't settled. It changes all the time.

(4) OPINION: EUROPE'S CARBON CON JOB

The Wall Street Journal, 21 August 2007

<http://online.wsj.com/article/SB118764555108003341.html>

By KYLE WINGFIELD

With all the supposed truths out there about global warming, here's one that doesn't get reported very often. Europe isn't the climate-change champion that its leaders, and their American apologists, would have you believe.

It's true that emissions -- both in absolute terms and on a per capita basis -- remain higher in America than in the EU-15 (the countries that belonged to the European Union before its 2004 expansion, and which are widely used as a comparison for the U.S. when the subject is global warming). And when it comes to decrying the planet's impending doom and making grand gestures about preventing this, Europe is second to none.

Let's assume, though, for argument's sake, that most Americans believe global warming is a real danger, that carbon dioxide is public enemy No. 1, and that the only question is what to do about it. Before following Europe's lead in adopting a cap-and-trade system or mandatory renewable energy targets, wouldn't you want to know that those actions will lead to something better than the status quo?

So would I. And the numbers show that if America is the Great Carbon Satan, Europe is certainly no angel.

Since 2000, emissions of CO2 have been growing more rapidly in Europe, with all its capping and yapping, than in the U.S., where there has been minimal government intervention so far. As of 2005, we're talking about a 3.8% rise in the EU-15 versus a 2.5% increase in the U.S., according to statistics from the United Nations.

What's more, preliminary data indicate that America's CO2 output fell by 1.3% from 2005 to 2006. If these numbers hold up, it would mean U.S. emissions growth is nearly flat so far this decade. Europe hasn't yet released figures for last year, but it did report in June that emissions from the participants in its carbon-trading scheme, which account for almost half of Europe's CO2 production, rose slightly in 2006.

The news gets worse for Europe when you consider that during this decade, the U.S. population has grown at roughly double the rate of the EU-15 while the American economy has been expanding about 40% faster. It seems Europe is becoming less efficient in its carbon production while U.S. efficiency is improving.

Now, few people – this writer included – would look at these statistics and conclude that Europe should necessarily adopt America's more passive approach. When you talk about CO2 emissions during this decade, or even go back to the globally accepted "base year" of 1990, you're working with a small sample size. And there really isn't much difference between a change of 3.8% and one of 2.5%. So why would the U.S. instead want to adopt Europe's policies?

As a measure of the gap between Europe's rhetoric and its reality, nothing beats its emissions trading scheme. The idea is that CO2-intensive companies – chiefly those that produce power or use a great deal of it – receive a certain number of permits to emit the gas. If they reduce their emissions and end up with a surplus, they can sell the extra permits to firms needing more allowances. In this way, market mechanisms are supposed to punish or reward companies for their carbon output, encouraging them to reduce it in the long run.

In Europe, however, the "market" consists of demand that government has created artificially and – more important – supply that the state distributes arbitrarily. Not surprisingly, companies lobbied hard to ensure favorable allocations when trading began in 2005. The number of permits exceeded actual emissions and prices plummeted. Today, allowances for 1,000 tons of CO2 are priced at about 11 euro cents, hardly high enough to prod a company to cut its carbon instead of just buying more permits. If you think the U.S. Congress – whether led by Democrats or Republicans – would be more likely to shun special interests in the name of environmentalism, then I've got some tariff-free Brazilian ethanol to sell you.

Brussels claims it's correcting the system for the next trading period, which runs from 2008 to 2012, but a number of holes will remain. For instance, it's expected that companies will be able to buy permits outside the EU from other countries and then import them to cover their needs. A large influx of permits could depress prices in the same way that the EU's own overallocation did the first time around. That's particularly true if third countries are lax in their issuance of permits.

"These [non-EU] credits have already been exposed as highly flawed, and often fraudulent," Max Andersson, a Green member of the Swedish Parliament, wrote this month in a study for the think tank Open Europe. "They don't always reflect absolute reductions in emissions, whilst many of these credits are generated from projects in developing countries that would have happened anyway." The result, he concludes, is that emissions might not fall but rise.

Another potential problem: An energy-industry source says that, in many EU member states, the allocation will likely be done in a way that gives sufficient permits to most of the firms that use a lot of energy, leaving a shortage for electricity producers. There might be some logic in that – instead of relying on manufacturers to reduce their energy consumption, power companies would have more of an incentive to produce electricity in a way that doesn't create as much carbon in the first place.

It would only work, though, as long as the power companies didn't buy additional permits and pass the cost along to customers instead of investing in real carbon-cutting measures. It would require competition to keep them from that temptation, though, and there's the rub: The main players in large markets like France and Germany are still effectively insulated from rivals and can set prices as they wish. Brussels has been trying for years to create a pan-European energy market, but it may be the better part of a decade before it's finished.

European policy makers have plenty of motivation to goad Washington into going along with their approach before too many people realize it isn't working. At a summit in March, EU national leaders dramatically raised the stakes by pledging a 20% cut in CO2 emissions by 2020. That's a real laugh considering their scant chances of meeting their Kyoto commitment of 8% by 2012. Their move is best seen as a bluff intended to pressure the U.S. into the game. Here in Europe, the grand gesture is always the most appealing play.

(5) "POLICYMAKERS THINK WE KNOW MORE THAN WE ACTUALLY KNOW"

The Times, 21 August 2007
http://www.timesonline.co.uk/tol/life and style/career and jobs/public sector/article2294475.ece

Just how accurate are our weather-prediction models?

PREDICTING climate change is a tricky business, so thank heavens for computer programmes that can take a melting ice sheet here and an El Niño effect there and turn it into a recipe for disaster. But not so fast, says Lenny Smith, a statistician at the London School of Economics who is concerned by the "naïve realism" of climate modelling.

"Our models are being over-interpreted and misinterpreted," he told a conference organised by the British Antarctic Survey in Cambridge. "They are getting better; I don't want to trash them per se. But as we change our predictions, how do we maintain the credibility of the science? We need to drop the pretence that they are nearly perfect."

Smith singles out the British Government's UK Climate Impacts Programme and the Met Office for making detailed climate projections for regions of the UK when the global models vary widely.

Policymakers "think we know more than we actually know. We need to be more open about our uncertainties", Smith says.

But that's not to say that there's any good news on climate change, New Scientist (Aug 18) reports.

(6) HANSEN AND THE "DESTRUCTION OF CREATION"

Climate Audit, 20 August 2007
<http://www.climateaudit.org/?p=1946>

By Steve McIntyre

Hansen has followed up his "Lights Out Upstairs" outburst with another outburst dismissing critics as "court jesters" with whom he will have no truck. His new jeremiad re-iterated the position of NASA spokesman Gavin Schmidt that U.S. errors "didn't matter" because the U.S. was only 2% of the earth's surface. Today I'll take a look back at Hansen et al 1999 and, especially Hansen et al 2001, the latter entitled "A closer look at United States and global surface temperature change" and being entirely devoted to coaxing a few-tenths of temperature change out of the U.S. record, a matter now said to be unimportant. Hansen also linked interest in the NASA computer programming errors to somehow acquiescing in the "destruction of Creation".

Hansen's Recent Jeremiads

Hansen has a collection of his recent jeremiads online here. On August 10, 2007, shortly after NASA had changed their online data for over 1200 US HCN stations and for their U.S. temperature history, Hansen sent an email to reporters and others saying:

"Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. ... My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem, though."

As I will show below, Hansen himself thought otherwise in Hansen et al 2001 - an article which is devoted to nothing but this topic. Hansen's most recent epistle is well worth reading. The proximate occasion of this latest letter is Hansen's "Y2K" error. He says in the letter (but not at the NASA website) that the flaw affected temperatures in the U.S. "by about 0.15 deg C... only in 2000 and later" and that they patched the program, "thanked the fellow who pointed it out and thought that was the end of it."

Hansen says that he will not "joust" with his critics, who he regards as mere "court jesters", since "Creation" itself is at stake:

"If we, in effect, destroy Creation, passing on to our children, grandchildren, and the unborn a situation out of their control, the contrarians who work to deny and confuse will not be the principal culprits. The contrarians will be remembered as court jesters. There is no point to joust with court jesters. They will always be present. They will continue to entertain even if the Titanic begins to take on water. Their role and consequence is only as a diversion from what is important."

It's as though Hansen, who grew up in the 1930s and 1940s, has a Jor-El complex: Jor-El being familiar to young boys of

a certain age as Superman's father who (per Wikipedia):

"was a highly respected scientist on the planet Krypton before its destruction. He foresaw the planet's fate, but was unable to convince his colleagues in time to save their race. Jor-El was, however, able to save his infant son, Kal-El, sending him in a homemade rocketship to the planet Earth just moments before Krypton's demise."

(7) MEDIA RISK BIAS FEEDBACK

Don't we know it - Ed

Overcoming Bias, 20 August 2007

<http://www.overcomingbias.com/2007/08/media-risk-bias.html>

Anders Sandberg

Recently a friend mentioned that he was concerned about health effects from wifi. I pointed out that this was likely an overblown concern, fed by the media echoes of a scare mongering BBC Panorama program, and pointed him at the coverage at Ben Goldacre's blog Bad Science for a through takedown of the whole issue.

To my surprise he came back more worried than ever. He had watched the program on the Bad Science page, but not looked very much at the damning criticism surrounding it. After all, a warning is much more salient than a critique. My friend is highly intelligent and careful about his biases, yet fell for this one.

There exists a feedback loop in cases like this. The public is concerned about a possible health threat (electromagnetic emissions, aspartame, GMOs) and demand that the potential threat is evaluated. Funding appears and researchers evaluate the threat. Their findings are reported back through media to the public, who update their risk estimates.

In an ideal world the end result is that everybody get better estimates. But this process very easily introduces bias: the initial concern will determine where the money goes, so issues the public is concerned about will get more funding regardless of where the real risks are. The media reporting will also introduce bias since the media favour reporting newsworthy news, and risk tends to cause greater interest than reports of no risk (or the arrival of reviews of the state of the knowledge). Hence studies warning of a risk will be overreported compared to risks downplaying it, and this will lead to a biased impression of the total risk. Finally, the public will have an availability bias that makes them take note of reported risks more than reported non-risks. And this leads to further concerns and demands for investigation.

Note that I leave out publication bias and funding bias here. There may also be a feedback from the public to media making media report things they estimate the public would want to hear about. These factors of course muddy things further in real life but mostly seem to support the feedback, not counter it.

Subject: Annual Mean Temperature Station Data

From: @hotmail.com>

Date: Tue, 28 Aug 2007 07:00:47 -0500

To: <rruedy@giss.nasa.gov>

I am interested in obtaining monthly temperature data for all stations in the world in one ASCII file. Right now, the only way I see to get that is to download the monthly text data from each station by going through http://data.giss.nasa.gov/gistemp/station_data/.

Is there a way to obtain this information in one large file?

Thanks,

Subject: Re: Problem with data access

This looks like the typical little_endian/big_endian problem; character data are fine, but the interpretation of numerical data is chip-dependent. It seems your chips are of the little-endian variety.

If your compiler has an option like "-convert big_endian", then all you have to do is recompile the program invoking that option.

If you don't, the README.txt file that accompanied my program contains a routine swap.f . Again, there are 2 options:

- Either swap.f works as is and converts the data files into a form your compiler can handle
- or "swap" crashes; in that case delete from swap.f the section that starts with "c**** Try assuming ..." and ends with "c**** if the section above ...".

One (and usually only one) of these 2 versions of swap.f should do the trick.

Good luck and let me know if you have any further problems. In the worst case, you might tell me what you are trying to do, so I can convert whatever you need into a format that is appropriate for your purposes. But I am confident that the above instructions will allow you to do it yourself.

Reto Ruedy

Global Warming Debate Overheats With Bad Numbers

/(The following is a guest post by The Wall Street Journal's Keith Winstein. Carl Bialik will be back tomorrow.)/

Did a blogger fix a calculation error in NASA's global-warming records, making 1934, and not 1998, the hottest year on record?

Well, no.

Commentators erupted last week with the news that Stephen McIntyre, a Canadian mathematician and blogger, had found a mistake in U.S. temperature records maintained by the National Aeronautics and Space Administration. In fixing the problem, NASA was said to have destroyed a central plank of support for global warming.

"A blogger's recalculation of NASA data puts 1934, not 1998, as the warmest year on record," read a front-page blurb Friday on the New York Times Web site, pointing to a Times opinion blog. "Among global warming Cassandras, the fact that 1998 was the 'hottest year on record' has always been an article of faith."

"NASA has now silently released corrected figures, and the changes are truly astounding," wrote a blogger at dailytech.com. Even Rush Limbaugh devoted a chunk of his radio program to the issue, saying, "One of the central tenets of the global warming hoaxers today is that 1998 was the hottest year in history on record... It turns out that the statistics, the temperature data that NASA used to compile the temperatures in 1998 is wrong."

But the commentators are mistaken. Part of the story is true: Mr. McIntyre, a former mining-industry executive who is well-known for efforts to scrutinize climate-change data, did find a calculation error in a NASA Web

page listing the average U.S. temperatures over the last 127 years. NASA had been combining thermometer data from two different sources -- one until 1999, and another source for afterward. But the two sources had been calibrated differently, and the agency hadn't properly accounted for the difference. Mr. McIntyre pointed the error out to scientists at NASA, who posted a revised file last Tuesday. And the revised file did list 1934 as slightly warmer, in the continental U.S., than 1998 -- by 1/50th of a degree Celsius -- though it turns out the flaw discovered by Mr. McIntyre had nothing to do with that. More on this last point in a moment.

In an interview, Mr. McIntyre said he just wanted NASA to be more transparent about how it calculates the annual temperature averages.

"The reaction in the right-wing blogosphere is overwrought," Mr. McIntyre said.

"I certainly haven't said that this is some kind of magic bullet that disproves global warming." Mr. McIntyre's real beef is that he thinks the

country's weather stations need auditing. On his blog www.climateaudit.org, Mr. McIntyre takes the position that climate scientists should post their complete data and computer code to allow others to audit their conclusions, and he's concerned about the effect on the NASA

flaw on scientists who may have relied on the data. "I'm not saying that it hasn't gotten warmer. There's lots of evidence that it has gotten warmer. It doesn't mean you don't sort out the quality of your stations," he said. (Mr.

McIntyre was featured in a front-page article in The Wall Street Journal about his criticism of another climate science paper that estimated temperatures over the last thousand years.)

Pegging the "warmest year" in the U.S. is difficult. Because there are fewer thermometers measuring temperatures in the U.S. than in the whole world, estimates of the average U.S. temperature are less precise than those for the globe. Reto A. Ruedy, a NASA scientist who helps calculate the data, said NASA's measurements of average yearly temperature in the continental U.S. have a margin of error of 0.47 degree Celsius. As a result, at least 12 years out of the last 127 can claim to be in a statistical tie for warmest in the U.S. NASA's correction concerned only U.S. temperatures, meaning it has little or no bearing on the "global" warming argument. Global warmest has been something of a moving target: The Intergovernmental Panel on Climate Change wrote in 2001 that 1998 was the warmest year on record, but that conclusion was made obsolete by 2002, 2003, 2004, 2005 and 2006 -- all of which were also quite warm.

Back in the U.S., it turns out 1934 and 1998 have been swapping (statistically insignificant) spots on the ranking for a number of

years.

Mr. Ruedy said NASA downloads new thermometer data every month, and recalculates annual average temperatures based on things like thermometer calibrations, "urban warming" corrections and other adjustments. In 2001's calculations, 1934's average was warmer by a very slight amount. By 2006, 1934 and 1998 were at an exact, not just statistical, tie (NASA rounds the figures to the nearest hundredth of a degree Celsius). In an early 2007 update, 1998 had edged ahead, but by July, 1934 was back on top by 1/50th of a degree Celsius. All of these movements were the result of NASA's calibrations, not the flaw identified by Mr. McIntyre. The latest shift showed up on NASA's Web site when it did because the agency incorporated all of its latest data online when it was making the unscheduled update to address the flaw Mr. McIntyre spotted.

Mr. McIntyre said he doesn't contest the notion that the flaw he identified had nothing to do with the change in ranking for 1934 and 1998. He has exchanged e-mail with Mr. Ruedy about the flaw, but not on that issue. (The two have a less-than-cordial relationship after another dust-up earlier this year.) In the view of NASA's Mr. Ruedy, the fact that 1934 and 1998 were well within the margin of error before (and still are) makes it silly to try to rank them. "This is totally ridiculous," Mr. Ruedy said. "Lots of noise about noise."

Best,
Keith

Unfortunately, I don't seem to be set up to get to your web site because of a "precondition failed" error and our web master is on vacation.

Is there any way you could email your article to me - I'd be very interested to see what came out of our conversation.

Cheers,

Reto

Thanks, this is very interesting -- even playing this "which is numerically higher" game (if you will indulge that for a bit more), the correction did not affect the relative ordering of the years. 1934 was at 1.25 before and after the correction, and 1998 was at 1.23 before and after the correction.

Do you have any idea why the "before correction" data doesn't match the version that Google downloaded on July 23, 2007 from <http://data.giss.nasa.gov/gistemp/graphs/Fig.D.txt> ?

<http://64.233.169.104/search?q=cache:vskwzroreeQJ:data.giss.nasa.gov/gistemp/graphs/Fig.D.txt+http://data.giss.nasa.gov/gistemp/graphs/Fig.D.txt&hl=en&ct=clk&cd=1&gl=us&client=firefox-a>

In that version, 1934 was at 1.23 and 1998 was at 1.24.

Perhaps the July 23 2007 version had not yet incorporated the June 2007 data? Any insights would be much appreciated.

Thanks, and best regards,
Keith Winstein

Yes, if that's the case, it does seem like this kerfluffle is totally unrelated to the year-2000 correction. (Or at least, even if you had never fixed the bug, the new files posted in February 2008 would have caused a kerfluffle.)

Thank you so much for all your time.

Regards,
Keith

On Fri, 10 Aug 2007, Reto Ruedy wrote:

Hi Keith,

We compute these means every month, but since these are annual means, they are copied to the web site only once a year (on February).

So the change that caused all the havoc must have happened after one of the previous routine updates.

Thanks for noticing that,

Reto

Not sure which 2001 paper you are referring to:

Hansen, J.E., et al. 2001: A closer look at United States and global surface temperature change. J. Geophys. Res.

is at http://pubs.giss.nasa.gov/abstracts/2001/Hansen_etal.html

Hansen, J.E., and Mki. Sato, 2001: Trends of measured climate forcing agents. Proc. Natl. Acad. Sci.

is at http://pubs.giss.nasa.gov/abstracts/2001/Hansen_Sato.html

I assume the 1981 paper is Hansen et al. rather than Lacis et al.

Hansen, J., et al. 1981: Climate impact of increasing atmospheric carbon dioxide. Science

is at http://pubs.giss.nasa.gov/abstracts/1981/Hansen_etal.html

Makiko,

I generally prefer that when people link to docs on the website that you use the HTML page which has the "Download PDF" link rather than point directly at the PDF file itself.

The word "are" all caps in the third paragraph out to be changes to lower case and put in bold. Being in all caps right now and close to the abbreviation GHCN, it almost looks like it too is an abbreviation.

When I view the Word DOC there is no degree sign in 0.15 deg-C. Is that intentional?

The phrase "order one-thousands" should be "order one-thousandth".

A Light On Upstairs?

Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. and a thousandth of a degree over the world.

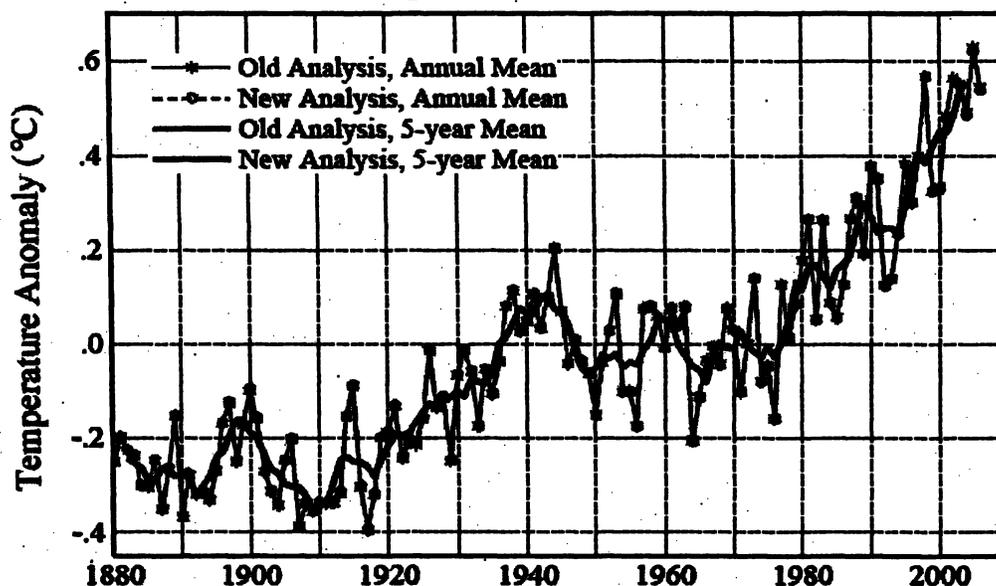

Recently it was realized that the monthly more-or-less-automatic updates of our global temperature analysis (http://pubs.giss.nasa.gov/abstracts/2001/Hansen_etal.html) had a flaw in the U.S. data. In that (2001) update of the analysis method (originally published in our 1981 Science paper – http://pubs.giss.nasa.gov/abstracts/1981/Hansen_etal.html) we included improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations are in the GHCN (Global Historical Climatology Network) data stream, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in 2001 in the records at those stations, some up, some down (over U.S. only). This problem is easy to fix, by matching the 1990s decadal-mean temperatures for the NOAA-corrected and GHCN records, and we have made that correction.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15°C, as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousandth of a degree, so the corrected and uncorrected curves are indistinguishable.

Global Temperature (Land-Ocean Index)

Contrary to some of the statements flying around the internet, there is no effect on the rankings of global temperature. Also our prior analysis had 1934 as the warmest year in the U.S. (see the 2001 paper above), and it continues to be the warmest year, both before and after the correction to post 2000 temperatures. However, as we note in that paper, the 1934 and 1998 temperature are practically the same, the difference being much smaller than the uncertainty.

Somehow the flaw in 2001-2007 U.S. data was advertised on the internet and for two days I have been besieged by rants that I have wronged the President, that I must "step down", or that I must "vanish". Hmm, I am not very good at magic tricks.

My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem, though.

Please read this remark of Robert's and make the change unless you really want it to be ARE.

When I view the Word DOC there is no degree sign in 0.15 deg-C. Is that intentional?

I think SI unit doesn't have degree symbol, so just 0.15C, but I think it is clearer to have the usual small circle high up or write down deg. Jim made it 0.15C, so maybe he is using the SI unit.

The phrase "order one-thousands" should be "order one-thousandth".

Yes, you are right. I will make the change.

When I view the Word DOC there is no degree sign in 0.15 deg-C.
Is that intentional?

I think SI unit doesn't have degree symbol, so just 0.15C, but I think it is clearer to have the usual small circle high up or write down deg. Jim made it 0.15C, so maybe he is using the SI unit.

The phrase "order one-thousands" should be "order one-thousandth".

Yes, you are right. I will make the change. (By the way, now in Japan a song called "I am a thousand winds" is very popular.)

A Light On Upstairs?

Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. and a thousandth of a degree over the world.

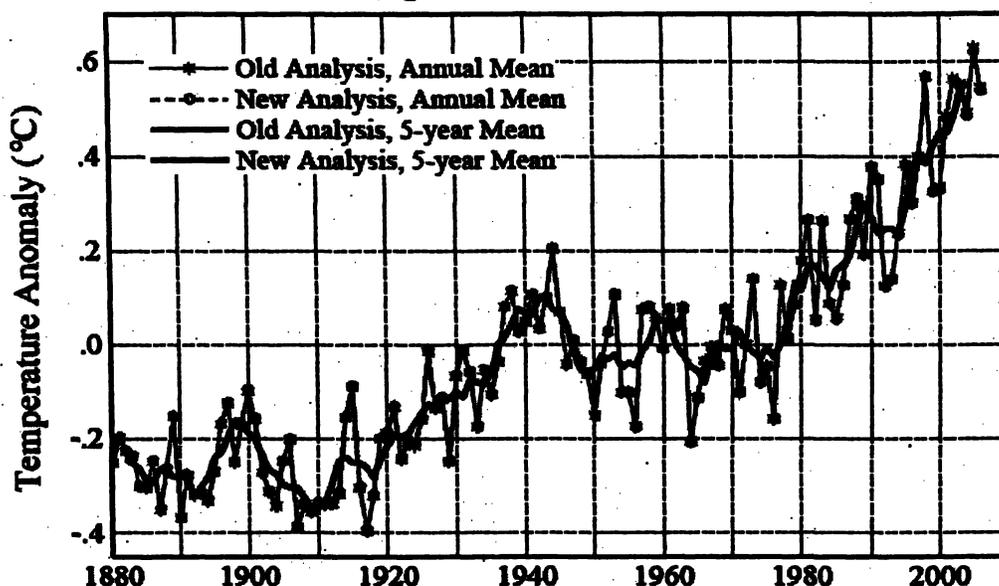

Recently it was realized that the monthly more-or-less-automatic updates of our global temperature analysis (http://pubs.giss.nasa.gov/abstracts/2001/Hansen_et_al.html) had a flaw in the U.S. data. In that (2001) update of the analysis method (originally published in our 1981 Science paper – http://pubs.giss.nasa.gov/abstracts/1981/Hansen_et_al.html) we included improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations are in the GHCN (Global Historical Climatology Network) data stream, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in 2001 in the records at those stations, some up, some down (over U.S. only). This problem is easy to fix, by matching the 1990s decadal-mean temperatures for the NOAA-corrected and GHCN records, and we have made that correction.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15°C , as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousandth of a degree, so the corrected and uncorrected curves are indistinguishable.

Global Temperature (Land-Ocean Index)

Contrary to some of the statements flying around the internet, there is no effect on the rankings of global temperature. Also our prior analysis had 1934 as the warmest year in the U.S. (see the 2001 paper above), and it continues to be the warmest year, both before and after the correction to post 2000 temperatures. However, as we note in that paper, the 1934 and 1998 temperature are practically the same, the difference being much smaller than the uncertainty.

Somehow the flaw in 2001-2007 U.S. data was advertised on the internet and for two days I have been besieged by rants that I have wronged the President, that I must "step down", or that I must "vanish". Hmm, I am not very good at magic tricks.

My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem, though.

Subject: Re: FW: McIntyre Interview

From: @gmail.com>

Date: Thu, 16 Aug 2007 16:09:45 -0400

To: lesgiss

CC: rschmunk@giss.nasa.gov, rruedy@giss.nasa.gov, jhansen@giss.nasa.gov, lmccarthy@giss.nasa.gov, gschmidt@giss.nasa.gov

Hi all,

I am so hence the GMail address as I respond to the e-mail.

Gavin has the essentials correct in responding to Les's question.

On about May 16, around 10:30 or 11:00 p.m. as I was getting ready to leave GISS for the night, I belatedly checked the error logs on the two web servers and discovered that there were several thousand errors in the log on Web2. On a normal day there would be about 500.

The errors in question were all for addresses which didn't exist in either CGI area or in the "work space" area for the GISTEMP station data script. Further investigation revealed that someone had been firing off requests to Web2 since about 2:00 that afternoon for the station data and by the time I looked into the situation, there had been at least 16,000 requests. Perhaps half of these had gone to addresses in the CGI directory, which means that activating CGI scripts to extract data, etc.

The identity of the computer making the requests was consistent, and as best I recall was something in the domain of Rogers Communications, a Canadian phone company and ISP.

Plainly this activity was from an "automated" agent, which in rough parlance is usually called a "robot". Many robots have legitimate purposes, e.g. search engines such as Google or Yahoo, but others do not (spambots), and others one just doesn't know.

As the robot on May 16 came from a generic ISP address rather than, say, an academic address and further because it's "user-agent" tag provided no further information about who was running it, and also because the GISS websites have "robots.txt" files which instruct all well-behaved web robots to stay out of the CGI directories, I cut off access to the ISP in question to the websites on Web2.

The next day I received e-mail from McIntyre asking what was up. He did not identify himself or on whose behalf he was acting.

At some point Reto got involved in the communications, and he must have mentioned to Jim what was up. Later on Reto indicated to me that Jim had said to go ahead and re-grant McIntyre access to the material.

I do not know if at any point McIntyre actually asked Jim or Reto if it was possible to obtain the GISS copy of the station data in a single or small number of files. All I know is that my first contact with him came because he was blasting umpteen thousand requests at the webservers.

I have no idea how much traffic McIntyre's website gets, and I don't know that I have ever even looked at it. His tone in his e-mail was on

the arrogant side, so I had no desire to prolong communication with him any longer than was necessary.

CC: Makiko Sato <makis@giss.nasa.gov>, Ken Lo <klo@giss.nasa.gov>, Jeff Berry <jberry@giss.nasa.gov>

Reto, et al.,

There are a couple issues here that I should probably point out.

The Python on Web2 is version 2.2. This is pretty old (Feb 2003) and should probably be updated. It was installed two years ago using an RPM from the IBM website, and the RPMs are rarely current. The current Python is 2.5.something.

I mention that because my experience on Web1 several years ago when trying to update the Python there was that "compiled" Python modules (a few of which the station data scripts make use) end up with version information embedded, and if you use a module compiled with one version of Python with a different (more recent) Python install, you can see a ton of warning msgs get fired off. On the webservers, this means that the Apache error_log gets filled up with warning msgs, and real error msgs are harder to notice.

More problematic is that the GISTEMP station data relies on a binary database file in BDB format. The current process is that when the GISTEMP data are updated on the machine Jay, a copy of this file (or multiple files) are created, they get copied over to Web2, and a little script has to be run to update the files from the older BDB on Jay to the newer BDB on Web2.

Personally, I'd love it if we could ditch the BDB files entirely, as this would remove an element from the process which I suspect no one currently at GISS understands. Further, if we were using a file format which we did (better) understand, it would make it possible in the future to just hand off the big file and some documentation about its format to persons inquiring about the station data. This would be a double plus, as hopefully we would also no longer have to worry about idiots writing robot scrapers to extract all the station data from the website.

And regarding the GISTEMP homepage, yes, it has looked rather cluttered for some time. I am in favor of anything to simplify the appearance and to shuffle some of the info off to new pages.

On Aug 27, 2007, at 19:20, Reto Ruedy wrote:

Hi Robert,

We'll need your help with two things:

1 - We'll simplify the main gistemp page but want to create links to pages that describe exactly what we do. Once I have a preliminary version of the text, I'll need your help to present it properly.

2 - We'd like to port what we do currently on the machine jay to some other machine, at least the python part that has to do with the data base system bdb . Ken Lo tried it but had problems using the version of python installed on discover (a Goddard machine).

Maybe, we can get it to work on web2 - but I'm sure we need your help with that. We should also ask systems to install python on at least one other machine (athena), so we have another backup.

By the way, I changed the format of the output of the station data tables that can be created on our web site, replacing all x.x0 by x.x for the monthly and seasonal means, I left 2 digits for the annual mean.

On Mon, 2007-08-27 at 18:42 -0400, James Hansen wrote:

This is excellent. This is consistent with the philosophy described in our 2001 paper, i.e., letting NOAA do the primary, labor-intensive task of cleaning U.S. station data. But it is appropriate for us to do our own urban correction using satellite night lights. I believe that they (NOAA) have underestimated urban warming effects, so it is better that we keep our own urban correction.

By the way, in case there is any question about why we get into this (surface temperature analysis) business at all, given NOAA's responsibilities: originally (in the 1970s) this was because there was no global analysis, the only available analysis being Murray Mitchell's, which only went down to 20N latitude. We showed that Southern Hemisphere coverage was actually useful, because of the large correlation distance of anomalies.

Funny thing is that, despite the much larger (person-wise) efforts that the other groups put into this, our analysis scheme still proved useful in 2005. The reason that we found 2005 (slightly) warmer than 1998 was that we included the full Arctic. And satellite IR data suggest that, if anything, our Arctic anomalies underestimate the actual positive anomalies there.

Jim

At 05:49 PM 8/27/2007, Reto Ruedy wrote:

Gavin,

Yes it was done properly this time - also, just looking at the annual US-means, that method seems to do pretty well. Steve will find the few stations where it didn't.

I thought of taking any detailed descriptions out of the "Background" section with links to separate pages, where the processes are carefully described and which are updated, whenever a change is made, noting the date when the change occurred. That should satisfy most people.

~~Rounding to the nearest .1C was Phil Jones' suggestion; I realize that we have to wait a while to do so.~~

Reto

On Mon, 2007-08-27 at 17:14 -0400, Gavin Schmidt wrote:
that's one less thing to worry about!

I wouldn't recommend changing the format - any such change is bound to be interpreted as an attempt to spin the numbers.

I take it that the 2006, 2007 numbers from GHCN are offset so that there is no discontinuity when going from USHCN to GHCN as you did for the post 2000 numbers in the last analysis?

If and when Jim decides to adopt this, I also recommend that we have a specific page outlining the change and the differences it makes so that there is no accusation that we're quietly fiddling the numbers.

thanks,

Gavin

On Mon, 2007-08-27 at 16:37, Reto Ruedy wrote:

Hi Jim,

Over the weekend, I used the newest version of the USHCN data to redo

our analysis; I did it twice, with and without the data USHCN filled in.

No surprises; between 1920 and 2005 the change in the US ann. means was

less than 0.02 C, the largest difference was in the 1880's

(<0.16 C).

With the new data, the US trend will be slightly higher.

The only interesting thing was, that my first attempt to process these

data failed. It turned out that our program could not handle the attempt

to remove data that were not present.

All went fine when I took the US stations off our list of manual

corrections.

It seems that all our manual deletions of parts of USHCN data were also

either deleted or modified in the new USHCN data. Their more rigorous

purging of odd-looking beginnings of station records seems to be the

main reason for the changes.

I suggest, we switch to the new USHCN data for future updates. It does

not matter much to keep or not to keep USHCN fillers; not keeping them

is a little more in line of what we did so far.

Hello Dr Ruedy,

My name is Michael Cassin. I'm developing some technology for hosting online datasets and statistical analysis, and would like to inquire about the possibility of reproducing the GISS temperature data. I realise it is available through the web interface, but would like to know if there is an ftp, or other, site where the entire dataset can be downloaded. I'd also like to be sure of any copyright issues.

Apologies for the direct intrusion into your inbox. I would understand if you redirect my inquiry.

Best regards,

Mike Cassin
Managing Director
Stikir Ltd

Subject: Python station data libraries

From: "Robert B. Schmunk" <Robert.B.Schmunk@nasa.gov>

Date: Tue, 4 Sep 2007 20:00:02 -0400

To: rruedy@giss.nasa.gov

Reto,

The "compiled stuff" for the station data is a group of C extensions to the Python code.

The compiled extensions are located on Web2 in the main Python libraries directory

/opt/freeware/lib/python2.2/site-packages

The source for these on Jay seems to be in the directory

/gcm/jglascoe/PYTHON/EXTENSIONS

The latter location is messy as there are Makefiles and other stuff. It's not sure whether all of the files are needed to actually generate the needed *.so files.

Reto,

Although I got the do_comb.sh script to run on Web2, the output is not the same as that generated on Jay.

The v2.mean.bdb file has the same length, but a close look with a hexedit program reveals that the binary data are not the same.

The other files all have different lengths.

I also mentioned trying to use Perl to read the BDB files, and with a little bit more effort I found it was actually pretty easy. Following is a little Perl program which can be run on Web2 and which prints out the info in the BDB file for an input station ID. One little oddity in the output is that the month data are in a slightly strange order; all the January data come first, then the February data, then etc.

Reto,

Although I got the do_comb.sh script to run on Web2, the output is not the same as that generated on Jay.

The v2.mean.bdb file has the same length, but a close look with a hexedit program reveals that the binary data are not the same.

The other files all have different lengths.

I also mentioned trying to use Perl to read the BDB files, and with a little bit more effort I found it was actually pretty easy. Following is a little Perl program which can be run on Web2 and which prints out the info in the BDB file for an input station ID. One little oddity in the output is that the month data are in a slightly strange order; all the January data come first, then the February data, then etc.

The file is just a plain text file. Save it to disk and open it with whatever plain-text editor you normally use. If you want to open it with Word or other fancy text editor, you might need to rename it so that it ends in ".txt".

Jim,

I prepared a documentation file (preliminary version attached) that divides the process into a preliminary and another 5 steps - Jay's programs are in step 1 and Robert is working on it (he has trouble compiling one of the C programs; also the order in which stations are combined seems dependent on the release of the data base system); I'm currently working on step 2 and Ken is working backwards from step 6 - hope to get through by tomorrow and combine it into a semi-coherent package.

A week seems a reasonable estimate to clean up what was missed - a total rewrite of Jay's programs however might easily take longer.

The C programs mentioned are actually compiled C "extensions" which are used by the Python programs. I was able to install a copy of these extensions on Web2 in the spring two years ago when we managed to transfer the various GISTEMP CGI scripts from Web1 to Web2, but unfortunately I do not have any record of what special hoops I had to jump through in order to do so.

As for the database system, the Python programs save the station data in binary files using Berkeley DB. The version of BDB on the machine Jay and on the machine Web2 is different.

I have been able to get a Python script which combines station data records to run on Web2, but there are some differences in the resulting output files when compared with the files generated on Jay. I am currently trying to figure out what might be the cause of that, and whether it might be a result of the difference in BDB versions.

To: rruedy@giss.nasa.gov

I have added the following files

```
/gcm/GHCN/BDB/sources_and_infiles/EXTENSIONS.tar.gz  
/gcm/GHCN/BDB/sources_and_infiles/EXTENSIONS_README.txt  
/gcm/GHCN/BDB/sources_and_infiles/listStats.py
```

The listStats.py is a module required by the comb_pieces.py script and was found in the Python1.5 library directory on Jay. Since it was not also in the Python2.2 library on Web2, I assume it is not part of the Python distro and needs to be included.

Depending on the size of the files involved, anything made available on Web2 could go in the web directories or the ftp directories. If neither the output_files subdirectory nor the v2.mean file is included in sources_and_infiles, then a tarball of the directory should be fairly small.

I'm not yet convinced that the problem with comb-records.py is resulting from something out of order in the database, or that records are even being examined out of order. But I haven't actually figured anything out yet...

On Sep 6, 2007, at 16:57, Reto Ruedy wrote:

No need to waste time on the differences - running programs on different machines gives different results, usually, of course, due to precision problems - here seemingly, because of the order things are accessed in a python library.

The main thing is to collect all programs and extensions as source codes, hopefully with a script that does all the necessary compilations or with instructions on how to do it.

If you can change the scripts on "jay" .../sources_and... with python extensions copied to a subdirectory of that directory so that we know what we have to copy to the web, something like that would be helpful. Also, how should it be made available - some tar-file down loadable from our website ?

Reto,

Earlier I noted:

I have been able to get a Python script which combines station data records to run on Web2, but there are some differences in the resulting output files when compared with the files generated on Jay. I am currently trying to figure out what might be the cause of that, and whether it might be a result of the difference in BDB versions.

It turns out that the difference is in the version of Python installed on the computer. More specifically, it's the Python hashing function.

There are a couple places in `comb_records.py` where the `records.items()` command is used to get the separate records from the hash (or what Python calls a "dict") for a station that has multiple records. It is characteristic of a hash/dict that the items could be in any order, and it is up to the programmer to do his own sorting if it is required that the items be processed in a predictable order.

So because the hash function in Python 1.5 and 2.2 differs, when `comb_records.py` examines a station with multiple records and decides which records to use, the order in which those multiple records are assessed may vary and that can affect the output file.

I created a modified version of `comb_records.py` which always works through multiple records for a station in a predictable order (0, 1, 2, etc.). When that program was run on Jay and on Web2, the resulting output files were the same.

A similar hash ordering issue probably applies to the `comb_pieces.py` program.

here is draft e-mail. I am still writing the 'history' introduction to
the program listing.

"Peak Oil" Paper Revised and Temperature Analysis Code

To be removed from Jim Hansen's e-mail distribution respond with
REMOVE in subject line.

(1) The paper "Implications of 'Peak Oil' for Atmospheric CO2 and
Climate", recently revised and resubmitted to Environmental Research
Letters, is available at XXXXXXXXXXXX.

A principal concern of both referees was our use of a pulse-response function, fit to the Bern carbon cycle model, as opposed to a detailed carbon cycle model. We have clarified limitations of a pulse-response function, but frankly we consider the simplicity and transparency of this approach to be a merit, not a fault. We are concerned mainly with scenarios that have a chance of avoiding "dangerous" CO2 levels, in which case the strong positive feedbacks found in some climate-carbon models are less likely, and in any case such feedbacks only add to the dichotomy between scenarios with declining emissions and "business-as-usual" scenarios.

We have minimized reference to a "dangerous" atmospheric CO2 level to satisfy one of the referees. We retained one reference to our recent papers, which are published in peer-reviewed journals and, we believe, make a strong case that we are already close to a dangerous CO2 level.

The principal conclusion of this paper is that it is possible to keep atmospheric CO2 at a much lower limit than commonly assumed, provided that coal use is phased out except where the CO2 is captured and stored. This paper provides some of the rationale for the discussion in "Old King Coal II".

(2) Temperature Analysis Code

Reto Ruedy has organized into a single document as well as practical on a short time scale the programs that produce our global temperature analysis from publicly available data streams of temperature measurements. These are a combination of subroutines written over the past few decades by Sergej Lebedeff, Jay Glascoe, and Reto. Because the programs include a variety of languages and computer unique functions Reto would have preferred to have a week or two to combine these into a simpler more transparent structure, but because of a recent flood of demands for the programs, they are being made available as is. People interested in science may want to wait a week or two for a simplified version.

An introduction to the program description defines the scientific purposes. We have also made a few graphs that may help clarify the significance (or lack thereof) of criticisms in the blogosphere. The one aspect of our procedure where subjectivity could come into play is the choice of which stations are eliminated from the record. This is based on identifying the (small fraction of) stations that raise a red flag (e.g., deviation of 5 standard deviations are more, or a large temporal discontinuity, as defined in our papers). I compared the records of these stations were compared with records of the nearest stations; if these displayed similar features the records were retained. We provide here the list of stations eliminated.

Figure 1 shows maps of the 1880-2006 and 1900-2006 changes of global temperature with and without these stations, and Figure 2 shows the global mean temperature with and without these stations. The effect is practically imperceptible and clearly insignificant.

Another favorite target of those who would raise doubt about the reality of global warming is the lack of quality data from South America and Africa, a legitimate concern. You will note in our maps of temperature change some blotches in South America and Africa, which are probably due to bad data. Our procedure does not throw out data because it looks unrealistic, as that would be subjective. But what is the global significance of these regions of exceptionally poor data? As shown by Figure 1, omission of South America and Africa has only a tiny effect on the global temperature change. Indeed, where it makes a difference it increases the temperature change by (an entirely insignificant) 0.01C.

This is all the time that I intend to give to this subject, but in case you wonder why we subject ourselves to the shenanigans, there are scientific reasons, repeated here from the "history" introduction to the program description.

here is draft e-mail. I am still writing the 'history'
introduction to

the program listing.

"Peak Oil" Paper Revised and Temperature Analysis Code

To be removed from Jim Hansen's e-mail distribution respond with
REMOVE in subject line.

(1) The paper "Implications of 'Peak Oil' for Atmospheric CO2 and
Climate", recently revised and resubmitted to Environmental
Research
Letters, is available at XXXXXXXXXXXX.

A principal concern of both referees was our use of a pulse- response
function, fit to the Bern carbon cycle model, as opposed to a
detailed
carbon cycle model. We have clarified limitations of a
pulse-response function, but frankly we consider the simplicity and
transparency of this approach to be a merit, not a fault. We are
concerned mainly with scenarios that have a chance of avoiding
"dangerous" CO2 levels, in which case the strong positive feedbacks
found in some climate-carbon models are less likely, and in any
case
such feedbacks only add to the dichotomy between scenarios with
declining emissions and "business-as-usual" scenarios.

We have minimized reference to a "dangerous" atmospheric CO2
level to
satisfy one of the referees. We retained one reference to our
recent
papers, which are published in peer-reviewed journals and, we
believe,
make a strong case that we are already close to a dangerous CO2
level.

The principal conclusion of this paper is that it is possible to
keep
atmospheric CO2 at a much lower limit than commonly assumed,
provided
that coal use is phased out except where the CO 2 is captured and
stored. This paper provides some of the rationale for the
discussion
in "Old King Coal II".

(2) Temperature Analysis Code

Reto Ruedy has organized into a single document as well as practical on a short time scale the programs that produce our global temperature analysis from publicly available data streams of temperature measurements. These are a combination of subroutines written over the past few decades by Sergej Lebedeff, Jay Glascoe, and Reto. Because the programs include a variety of languages and computer unique functions Reto would have preferred to have a week or two to combine these into a simpler more transparent structure, but because of a recent flood of demands for the programs, they are being made available as is. People interested in science may want to wait a week or two for a simplified version.

An introduction to the program description defines the scientific purposes. We have also made a few graphs that may help clarify the significance (or lack thereof) of criticisms in the blogosphere. The one aspect of our procedure where subjectivity could come into play is the choice of which stations are eliminated from the record. This is based on identifying the (small fraction of) stations that raise a red flag (e.g., deviation of 5 standard deviations or more, or a large temporal discontinuity, as defined in our papers). I compared the records of these stations with records of the nearest stations; if these displayed similar features the records were retained. We provide here the list of stations eliminated.

Figure 1 shows maps of the 1880-2006 and 1900-2006 changes of global temperature with and without these stations, and Figure 2 shows the global mean temperature with and without these stations. The effect is practically imperceptible and clearly insignificant.

Another favorite target of those who would raise doubt about the reality of global warming is the lack of quality data from South America and Africa, a legitimate concern. You will note in our maps of temperature change some blotches in South America and Africa, which are probably due to bad data. Our procedure does not throw out data because it looks unrealistic, as that would be subjective. But what is the global significance of these regions of exceptionally poor data? As shown by Figure 1, omission of South America and Africa has only a tiny effect on the global temperature change. Indeed,

where it
makes a difference it increases the temperature change by (an
entirely
insignificant) 0.01C.

This is all the time that I intend to give to this subject, but in
case you wonder why we subject ourselves to the shenanigans,
there are
scientific reasons, repeated here from the "history"
introduction to
the program description.

A preliminary re-working of the GISTEMP homepage is at

http://data.giss.nasa.gov/gistemp/index_new.html

Although very long, it could go up as-is in place of the current GISTEMP homepage except that the links to the Columbia webpage stuff are not there yet (i.e., in the second para of the Aug 2007 update comments).

I am very concerned about linking directly to the PDFs on the Columbia webpage, whether here or on the graphs page as Makiko has already done, because it is transparent to the user that the PDFs are located on Jim's personal webpage. All they know is that they click on a link on a NASA webpage and they get a PDF. Hence the inattentive user (which would be most of them) would think the PDF is a NASA document.

So on Sunday I will try to make a pass through the PDFs and extract out the material which can be posted on a NASA webpage. I would assume this would mostly mean toning down or eliminating language re: skeptics and denialists.

Also, Makiko, I cleaned up the HTML of the "what's new" you put at the start of the graphs webpage. Is the "(a)", "(b)", "(c)" notation necessary? I left it there, but can't see that it needs to be there.

On 9/15/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Jim,

In the description of step2 (homogeneization) "urban" should be replaced by "urban and peri-urban" or "non-rural" or we may add a sentence to indicate that "small-town" stations are adjusted the same way as urban stations. Although it is mentioned at the end of the previous section, it should probably be repeated here to avoid accusations of inconsistency.

let's use: "urban and peri-urban (i.e., other than rural)" that makes an unambiguous definition of our categories

April 2006 modification:

Looking at maps based on ocean data alone, we noticed that the HadISST data (1880-1981) extended to regions containing sea ice, whereas the NOAA data (1982-present) did not. In order to get a more consistent time series, the HadISST part was restricted to the same ice-free regions as the NOAA data. Since the temperature of water containing ice is always near the freezing point, including data from such regions tends to artificially dampen any heating or cooling trend.

April 2006 modification: HadISST ocean temperatures are now used only for regions that are identified as ice-free in both the NOAA and HadISST records. This change effects a small number of gridboxes in which HadISST has sea ice while NOAA has open water. The prior approach damped temperature change at these gridboxes because of specification of a fixed temperature in sea ice regions. The new approach still yields a conservative estimate of surface air temperature change, as surface air temperature usually changes markedly when sea ice is replaced by open water or vice versa. Because of the small area of these gridboxes the effect on global temperature change was negligible.

The revised homepage is in place. This:

- * includes Reto's suggested edits.
- * links to a new webpage on the August 2007. This is just a slight rewording of the "Light Upstairs" post, but I thought it important to get it on the GISS website, because there are references in the homepage text to the figures in this post.
- * links to Jim's website re: Usufruct & the Gorilla, but I explicitly identify this as going to Jim's personal webpage. When time permits, we should try to shift applicable content from this post in an update page on the GISS website.
- * modifies the webpage layout so that the block of six image links are now a strip down the side of the page. I did this to get the start of the text up at the top of the webpage, and perhaps get more people to actually read some of it.

Robert,

There is also a typo in the September 2007 item in the sentence that starts: "Our quality control...."

... and all stations removed by it our available in a list.

should be replaced by

... and all station records removed by it are available in a list.
or better

... and a list of all station records removed by it is provided.

I also would replace "stations" by "station records" in the first (and also in the last) sentence of that item (since NOAA only removed parts - mostly the beginnings - of a station record, not the whole thing). Then, of course, the second sentence has to be adjusted also: "The records removed ... so we no longer remove any USHCN records."

In addition, it is not true that USHCN removed "all" the records that we used to remove, some of these records were changed, some stayed as they were. Sorry, that was my mistake. So here is my suggestion for that item:

September 2007: The ... through 2005). In this newer version, NOAA removed or corrected a number of station records before year 2000. Since these changes included most of the records that failed our quality control checks, we no longer remove any USHCN records. *) Our quality control is still applied to the non-USHCN stations and is described by Hansen et al. (2001). A list of all station records removed by it is provided. The effect ... *)

(No changes in the first and the last sentence)

*) On second thought, the September 2007 item starts out with the NOAA-1999 -> NOAA-2005 switch. Rather than describing the effect of that change, the rest of the item deals with our quality control, programs I would be hard pressed to even find, we have not used them in years. If I remember correctly, these programs flagged as suspicious many stations; then we looked at the annual or monthly plots of these stations and picked the data to be discarded.

So I would stop after "we no longer remove any USHCN records". By the way, the effect of that switch was a slight increase in the US trend (.04 C for the 1920-2006 change based on linear trends: .21C -> .25C for the 1920-2006 period), the global trends were not affected.

I think Jim is referring to a sentence at the end of the Sept 2007 paragraph in the "updates to analysis", where it says, "The effect of station removal on analyzed global temperature is very small, as shown by graphs and maps available here." That should apparently link to the graphs page, so I have added the missing link.

On Sep 18, 2007, at 18:06, Makiko Sato wrote:

What data comparison? The comparison due to the newest change, i.e. USHCN from 2000 to current version, is still there. I wrote "Tables: Global, US" in a separate line below the graphs, but now Robert changed to "Also see tables of comparisons for <http://data.giss.nasa.gov/gistemp/graphs/GLB_USHCN.2005vs1999.txt>globe and <http://data.giss.nasa.gov/gistemp/graphs/US_USHCN.2005vs1999.txt>US-only." as an additional sentence, so you may have not noticed it.

Otherwise, I don't remember the data comparison. I can make such things for USHCN/GHCN problem fixing.

Subject: Re: solar luminosity
To: James Hansen <jhansen@giss.nasa.gov >
Cc: Richard Stothers <rstothers@giss.nasa.gov >

Jim,

The past evolution of the Sun's luminosity depends on certain assumptions. For example, if the Sun had been slightly more massive in the past and had slowly lost mass, its previous luminosity need not have been significantly lower than today.

However,

on the standard assumption of a constant mass, the Sun's luminosity 4.5 Gyr ago was

0.70

of today's value.

The increase of L with time is very nearly linear -- you might take a look at the log(L) vs. t plot in Fig. 4 of Sackmann et al. (1993, Astrophys. J., 418, 457-468) and

the

accompanying text in Section 3.2.2. This is a standard reference, although many other references could be cited giving the same result. But this particular reference also calculates the evolution of the Sun far into the future.

Dick

At 03:16 PM 7/25/2007 -0400, you wrote:

Dick,

Do you know the most appropriate scientific reference for the trend of solar luminosity? It is commonly assumed that it was about 6% less at

the

time of the last snowball Earth, about 540 million years ago. Can I assume that it is increasing at a rate of about 10% per billion years,

and

that this might be about right for the last couple of billion years and perhaps the next billion? Thanks for any insight.

Reto,

I am being besieged by e-mails and calls about this, so we need to do something promptly, as there will be stories written today for publication tomorrow. Let me know what the chances are that you will be able to have the comparative global temperature curves that we discussed yesterday.

By the way, Makiko, do you remember if we ever make any statement about how different years ranked for the United States temperatures? There are several demands that we issue a press release correcting our wrong results and declaring that 1934 is now the warmest year on record in the U.S., also that 4 of the 10 warmest years were in the 1930s and only 3 in the last 10 years.

Let's try to remember what statements we made about US temperature

(1) In our 2001 paper

GISS 1934 warmest, USHCN 1998 warmest, difference being a few hundredths of a degree

(2) Summation

2001-2003, only global T
2004 US for 1950-2003 (no 1934)
2005-2006, global and low latitudes

(3) In January 2007, I showed on my "Some Extra" page which most people don't look
1934 1.23, 1998 1.24 and 2006 1.23

We made rankings to the public only for the global mean. NOAA ususally does for the US.

A Light On Upstairs?

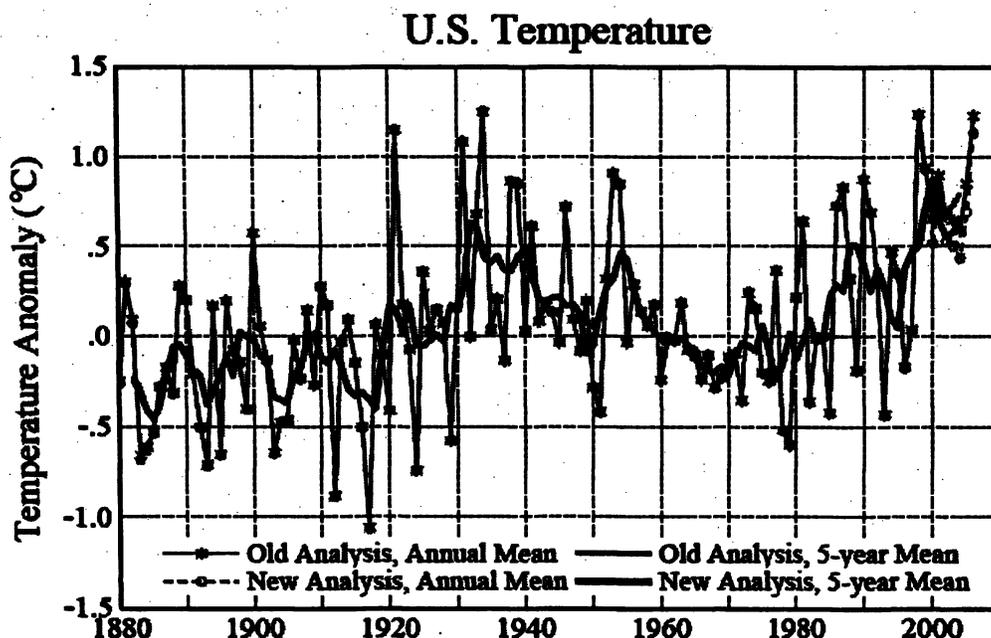

To be removed from Jim Hansen's e-mail list respond to sender with REMOVE as subject

Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. and a thousandth of a degree over the world.

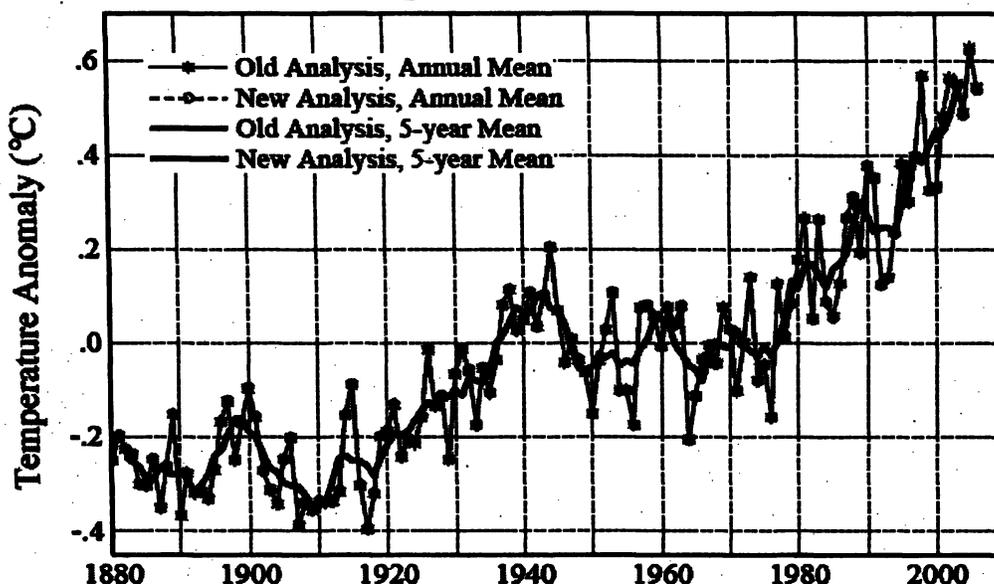

Recently it was realized that the monthly more-or-less-automatic updates of our global temperature analysis (http://pubs.giss.nasa.gov/docs/2001/2001_Hansen_etal.pdf) had a flaw in the U.S. data. In our most recent update of the analysis method (originally published in our 1981 Science paper – http://pubs.giss.nasa.gov/docs/1981/1981_Hansen_etal.pdf) we included improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations ARE in the GHCN (Global Historical Climatology Network) data stream, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in the records at those stations, some up, some down. This problem is easy to fix, by matching the 1990s decadal-mean temperatures for the NOAA-corrected and GHCN records, and we have made that correction.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15C, as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousandths of a degree, so the corrected and uncorrected curves are indistinguishable.

Global Temperature (Land-Ocean Index)

Somehow this data flaw was advertised on the internet and for two days I have been besieged by rants that I have wronged the President, that I must “step down”, or that I must “vanish”. Hmm, I am not very good at magic tricks.

I am always a bit puzzled by the views that seem to come from conservative extremes, a bit disconcerting as I come from a moderately conservative state and consider myself a moderate conservative in most ways – puzzling because it seems to me that conservatives should be the first ones standing up for preserving Creation and for the rights of the young and the unborn. After all, that is the basic intergenerational issue in global arming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15C, as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousandths of a degree, so the corrected and uncorrected curves are indistinguishable.

Global Temperature (Land-Ocean Index)

Somehow this data flaw was advertised on the internet and for two days I have been besieged by rants that I have wronged the President, that I must "step down", or that I must "vanish". Hmm, I am not very good at magic tricks.

I am always a bit puzzled by the views that seem to come from conservative extremes, a bit disconcerting as I come from a moderately conservative state and consider myself a moderate conservative in most ways – puzzling because it seems to me that conservatives should be the first ones standing up for preserving Creation and for the rights of the young and the unborn. After all, that is the basic intergenerational issue in global arming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem.

Jim

A Light On Upstairs?

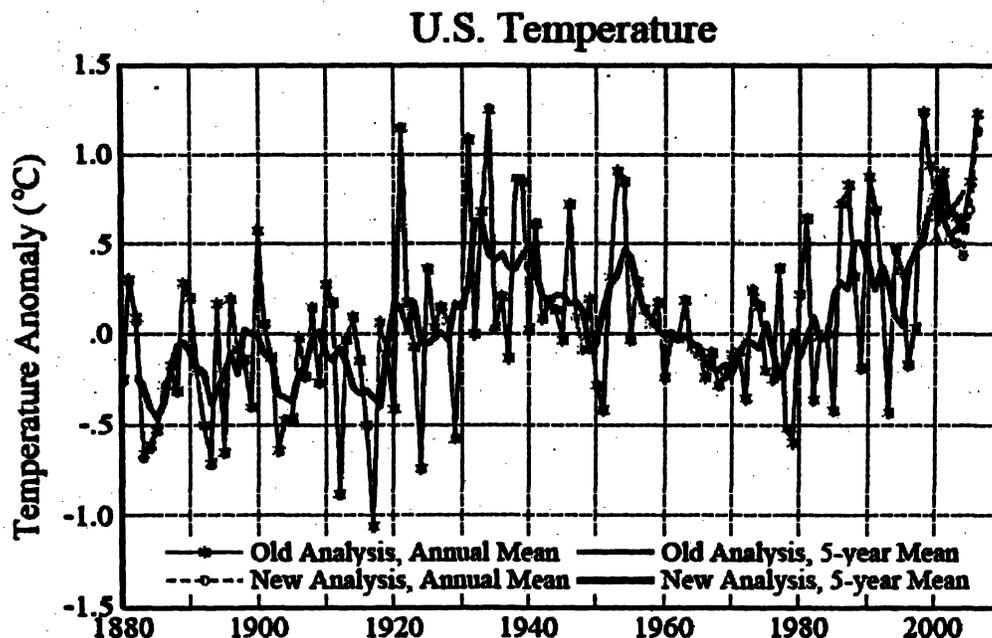

To be removed from Jim Hansen's e-mail list respond to sender with REMOVE as subject

Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. and a thousandth of a degree over the world.

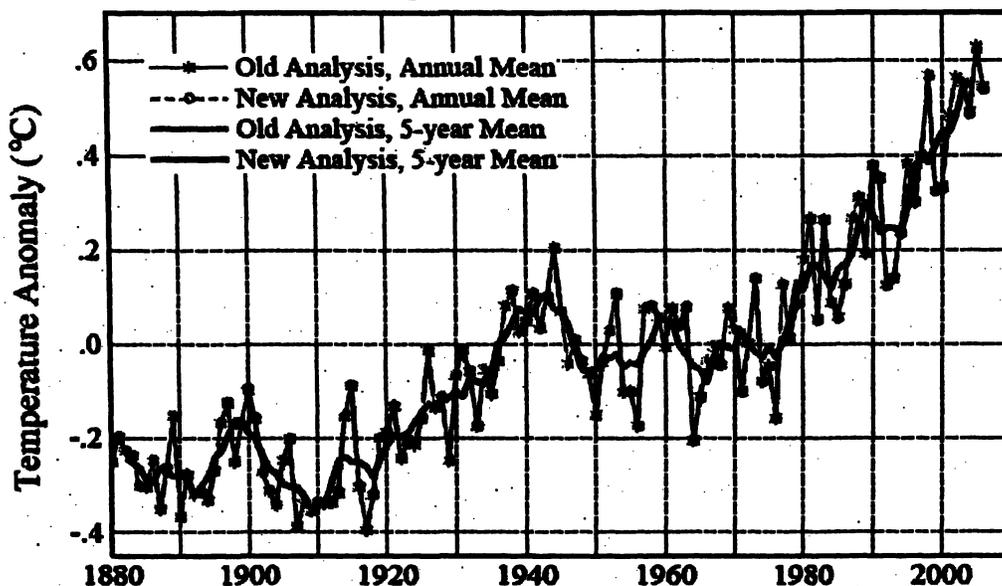

Recently it was realized that the monthly more-or-less-automatic updates of our global temperature analysis (http://pubs.giss.nasa.gov/docs/2001/2001_Hansen_etal.pdf) had a flaw in the U.S. data. In our most recent update of the analysis method (originally published in our 1981 Science paper – http://pubs.giss.nasa.gov/docs/1981/1981_Hansen_etal.pdf) we included improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations ARE in the GHCN (Global Historical Climatology Network) data stream, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in the records at those stations, some up, some down. This problem is easy to fix, by matching the 1990s decadal-mean temperatures for the NOAA-corrected and GHCN records, and we have made that correction.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15C, as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousands of a degree, so the corrected and uncorrected curves are indistinguishable.

I generally prefer that when people link to docs on the website that you use the HTML page which has the "Download PDF" link rather than point directly at the PDF file itself.

I don't understand this part. This is a Word file not HTML.

The word "are" all caps in the third paragraph out to be changes to lower case and put in bold. Being in all caps right now and close to the abbreviation GHCN, it almost looks like it too is an abbreviation.

Jim,

Please read this remark of Robert's and make the change unless you really want it to be ARE.

When I view the Word DOC there is no degree sign in 0.15 deg-C. Is that intentional?

I think SI unit doesn't have degree symbol, so just 0.15C, but I think it is clearer to have the usual small circle high up or write down deg. Jim made it 0.15C, so maybe he is using the SI unit.

The phrase "order one-thousands" should be "order one-thousandth".

Yes, you are right. I will make the change.

A Light On Upstairs?

Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. and a thousandth of a degree over the world.

Recently it was realized that the monthly more-or-less-automatic updates of our global temperature analysis (http://pubs.giss.nasa.gov/abstracts/2001/Hansen_et al.html) had a flaw in the U.S. data. In that (2001) update of the analysis method (originally published in our 1981 Science paper – http://pubs.giss.nasa.gov/abstracts/1981/Hansen_et al.html) we included improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations are in the GHCN (Global Historical Climatology Network) data stream, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in 2001 in the records at those stations, some up, some down (over U.S. only). This problem is easy to fix, by matching the 1990s decadal-mean temperatures for the NOAA-corrected and GHCN records, and we have made that correction.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15°C , as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousandth of a degree, so the corrected and uncorrected curves are indistinguishable.

Global Temperature (Land-Ocean Index)

Contrary to some of the statements flying around the internet, there is no effect on the rankings of global temperature. Also our prior analysis had 1934 as the warmest year in the U.S. (see the 2001 paper above), and it continues to be the warmest year, both before and after the correction to post 2000 temperatures. However, as we note in that paper, the 1934 and 1998 temperature are practically the same, the difference being much smaller than the uncertainty.

Somehow the flaw in 2001-2007 U.S. data was advertised on the internet and for two days I have been besieged by rants that I have wronged the President, that I must "step down", or that I must "vanish". Hmm, I am not very good at magic tricks.

My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem, though.

Makiko,

I generally prefer that when people link to docs on the website that you use the HTML page which has the "Download PDF" link rather than point directly at the PDF file itself.

I don't understand this part. This is a Word file not HTML.

The word "are" all caps in the third paragraph out to be changes to lower case and put in bold. Being in all caps right now and close to the abbreviation GHCN, it almost looks like it too is an abbreviation.

Jim,

Please read this remark of Robert's and make the change unless you really want it to be ARE.

When I view the Word DOC there is no degree sign in 0.15 deg-C.
Is that intentional?

I think SI unit doesn't have degree symbol, so just 0.15C, but I think it is clearer to have the usual small circle high up or write down deg. Jim made it 0.15C, so maybe he is using the SI unit.

The phrase "order one-thousands" should be "order one-thousandth".

Yes, you are right. I will make the change.

A Light On Upstairs?

Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. and a thousandth of a degree over the world.

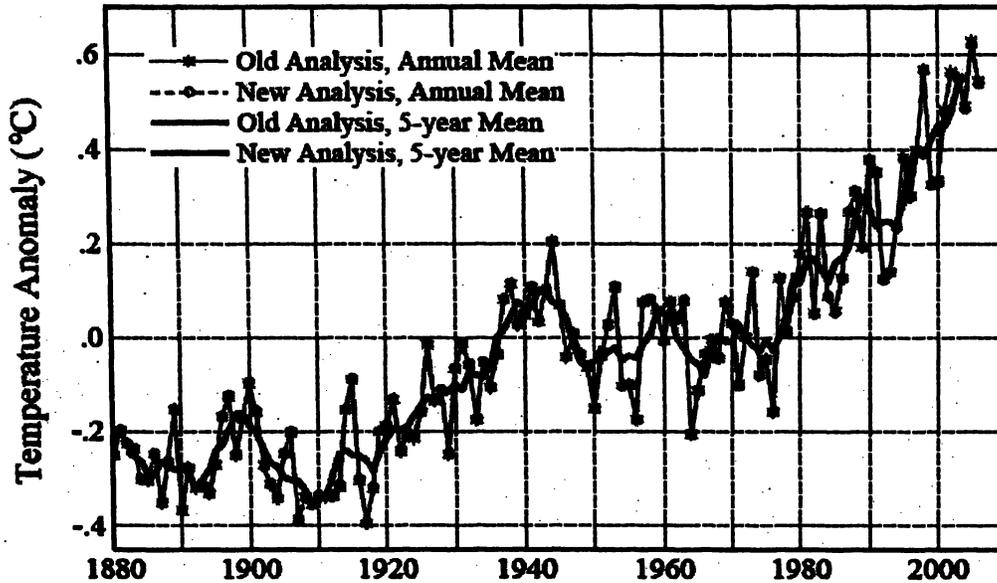

Recently it was realized that the monthly more-or-less-automatic updates of our global temperature analysis (http://pubs.giss.nasa.gov/abstracts/2001/Hansen_etal.html) had a flaw in the U.S. data. In that (2001) update of the analysis method (originally published in our 1981 Science paper – http://pubs.giss.nasa.gov/abstracts/1981/Hansen_etal.html) we included improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations are in the GHCN (Global Historical Climatology Network) data stream, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in 2001 in the records at those stations, some up, some down (over U.S. only). This problem is easy to fix, by matching the 1990s decadal-mean temperatures for the NOAA-corrected and GHCN records, and we have made that correction.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15°C, as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousandth of a degree, so the corrected and uncorrected curves are indistinguishable.

Global Temperature (Land-Ocean Index)

Contrary to some of the statements flying around the internet, there is no effect on the rankings of global temperature. Also our prior analysis had 1934 as the warmest year in the U.S. (see the 2001 paper above), and it continues to be the warmest year, both before and after the correction to post 2000 temperatures. However, as we note in that paper, the 1934 and 1998 temperature are practically the same, the difference being much smaller than the uncertainty.

Somehow the flaw in 2001-2007 U.S. data was advertised on the internet and for two days I have been besieged by rants that I have wronged the President, that I must "step down", or that I must "vanish". Hmm, I am not very good at magic tricks.

My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem, though.

Jim

A Light On Upstairs?

Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. and a thousandth of a degree over the world.

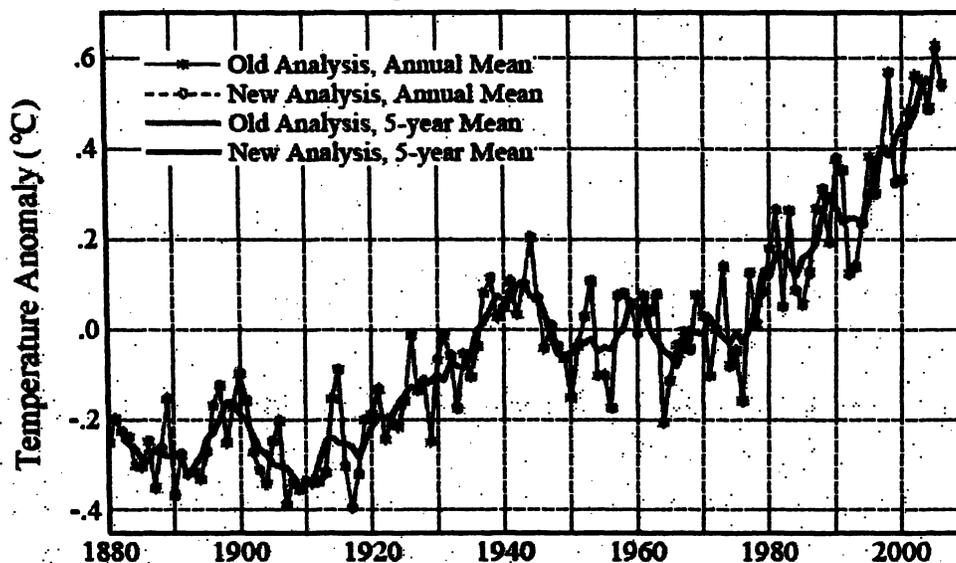

Recently it was realized that the monthly more-or-less-automatic updates of our global temperature analysis (http://pubs.giss.nasa.gov/abstracts/2001/Hansen_etal.html) had a flaw in the U.S. data. In that (2001) update of the analysis method (originally published in our 1981 Science paper – http://pubs.giss.nasa.gov/abstracts/1981/Hansen_etal.html) we included improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations are in the GHCN (Global Historical Climatology Network) data stream, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in 2001 in the records at those stations, some up, some down (over U.S. only). This problem is easy to fix, by matching the 1990s decadal-mean temperatures for the NOAA-corrected and GHCN records, and we have made that correction.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15°C, as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousandth of a degree, so the corrected and uncorrected curves are indistinguishable.

Global Temperature (Land-Ocean Index)

Contrary to some of the statements flying around the internet, there is no effect on the rankings of global temperature. Also our prior analysis had 1934 as the warmest year in the U.S. (see the 2001 paper above), and it continues to be the warmest year, both before and after the correction to post 2000 temperatures. However, as we note in that paper, the 1934 and 1998 temperature are practically the same, the difference being much smaller than the uncertainty.

Somehow the flaw in 2001-2007 U.S. data was advertised on the internet and for two days I have been besieged by rants that I have wronged the President, that I must "step down", or that I must "vanish". Hmm, I am not very good at magic tricks.

My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem, though.

Jim

Reto,

On Tuesday, using your new corrected data for the US temperature through July 2007, I updated the maonthly line graph, the set of the monthly maps, the US mean line graph and one extra set of 2007 vs. 1998 and 2005 line graph and maps (there are some people interested in this extra one and I sometimes get some e-mail about this, but I can remove it if you think it is no appropriate), but Makoto was sick and I didn't come in on Wednesday, Thursday Jim wanted me to do somethig else, and Friday as you know we were crazy for Jim's e-mail, so

I didn't have a chance to update annual mean data shown in Fig.A or Fig.A2, thinking the difference betwenn the original and corrected must be less than 0.01 degrees, but because of that correction together with the additional data (7 months difference in the whole data set may not be 7 months only for some stations), it is possible that the change from what I made in January, 2007 and your new table is 0.01 or more. I will update Fig.A.txt and Fig.A2.txt tomorrow.

Makiko

On 8/12/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Gavin,

It took me a while to solve the mystery of small differences between plots and tables, since both products are created from the same binary data set. Here is the solution:

My program produces the tables (txt files) with nint(100*data) and the plot files with "write F9.3" from the same data.

Makiko then rounds the plot file from 3 to 2 digits (F9.2) which is reasonable given the margin of error. Had I used F12.6, the number of differences would be almost zero, had I used F9.2 there would be no differences.

I used F9.3 because occasionally I was asked whether a small change was increased or decreased by roundoff - but I'll gladly change to F9.2 for future updates.

What I think would be more beneficial is to add (as we do in 1 isolated instance) an estimated margin of error to all our tables and plots, indicating how much we trust these numbers. It is a little complicated by the fact that they are a function of time, but giving one number for the early period and a second number for the last few decades should be sufficient.

I also think it would pay to take a look at the "graphs" section, drop or add some displays, and add to each display a small text indicating what we can (or cannot) learn from it, why one would be interested in it. Right now, it looks to me more like a random selection of graphs with a few maps thrown in for good measure.

To: James Hansen <jhansen@giss.nasa.gov>, rruedy@giss.nasa.gov

Jim, Reto,

I just came in to update the station based and land-ocean temperatures so that my tables Fig.A and Fig.A2 will have exactly the same numbers as Reto/Ken's tables. First I will make a directory called alp:/gcm/maki/Tsurface/store and save all global mean and US mean linegraph data I still have somewhere in my workstation, so that in case something like this happens we can look back old data. Since it doesn't take much space, I will save these data sets every month from now on.

If you have some suggestions/questions, please let me know.

Makiko

Right now, it looks to me more like a random selection of graphs with a few maps thrown in for good measure.

Reto

Reto,

When I took over from Jay when he left (Jay displayed what Jim told him to, based on our 1999 temperature paper), the graph section had only five graphs.

Fig. A, global mean, annual mean using meteorological stations (Fig. 4 of the paper)

Fig. B, northern, low, southern latitude annual means (Fig. 5 of the paper)

Fig. C, global mean, monthly means (Fig. 8 of the paper)

Fig. D, U.S. mean, annual means (Fig. 6 of the paper)

Fig. E, global and low latitude means, seasonal means (Fig. 7 of the paper)

I added

Fig. A2 (land-ocean index) because Jim switched more to land-ocean than the station data, and now this is our standard, and I don't think we should remove this.

hemispheric means, I put it because somebody I forgot (outsider) requested, and I thought it may not be a bad idea, but if you don't like this, I can remove.

set of recent months maps because Jim is quite interested in these, but since I have my own temperature page, I can remove this, if you want to.

And then the top one with a linegraph and three maps. As I mentioned earlier, some people like this, including Jim. But if you hate this, I can remove it also.

OK, I updated all versions of Fig.A and Fig.A2 with newest data with 3 digits after decimal, and manually typed in the table numbers to match Reto's tables. Since I did manually, there may be some mistakes. If you find some, please let me know.

Reto,

It would be good if you give me 4 digits. Thank you.

Makiko

At 17:29 2007/08/13, you wrote:

Makiko,

As you pointed out to me, if I keep 4 decimal places rather than 3, rounding to 2 digits will no longer be different than rounding directly to 2 digits (and I still have the 3rd digit if needed). So I will use 4 digits for internal purposes in the future.

On 8/13/07, James Hansen <jhansen@giss.nasa.gov> wrote:

Hi Reto,

Sorry that I didn't communicate clearly what I wanted to see in the new run of the analysis program. Two things need to be different from what Makiko showed me.

Reto,

He means the graphs you made and put in his mail box. When he got back from DC, I wanted to make sure he would take a look at them, so I picked them up from the mail box and handed him.

I am really sorry if I had misunderstood what you said. Actually I didn't see the graphs you made. Your newest computations for checking purpose had two changes at once, (a) all GHCN (no USHCN) and (b) all hundred some stations except St. Helena and Hawaii previously removed artificially are back, right?

Makiko

I know that the USHCN/GHCN business must be frustrating!, but...

First we cannot drop the NCDC improvements to the USHCN. There is no way that we can compete with the person-years of effort that they (Tom Karl and all the others at NCDC) put into that, and they are the experts. Also we have published it and we should continue to follow what we have in that (2001) paper. The correction that you made to stations post 2000 records (by setting the means for 1990 to be equal in the two records?) should be fine, and since we have made that available, we should use that. We don't want still another result, which would really set the pundits happy.

Second, what I want to see is how our new result compares with what we get if we make none of the changes in the table of changes, i.e., do not pick and choose any corrections (such as St. Helena) as being "obviously correct".

On 8/14/07, James Hansen <jhansen@giss.nasa.gov> wrote:

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it.

The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected by adding the NOAA/NCDC adjustment near the end of the record to the 2001-2007 data, and

it has been so corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the Washington Times (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century - 2000, 2002, 2003, 2004 - plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to

prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even American: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings - albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website

http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Jim,

Sorry, I have forgotten about the mean temperatures you told me when I was in my car this morning.

1880-1920 means

U.S. -0.2011 => -0.2054 (Before => is old analysis, after => is new analysis)

globe -0.2633 => -0.2618

These should not have changed, but they did because as I mentioned to you a few days ago, I don't have exactly the same data with and without recent corrections. The old data are what I made in January or March this year, so although they are annual means through 2006, they are slightly different by addition of some stations, etc.

1997-2006 means

U.S. 0.7751 => 0.6754

globe 0.4882 => 0.4844

Again in here, some portions of the change may be because I am NOT using exactly the same data with/without recent corrections.

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Don,

These are some desperate characters trying to make a mountain out of a mole hill.
I presume that my note "A Light on Upstairs?" should have clarified things for
scientists (Leslie, you can send it to anybody), but perhaps a few of additional
comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our
global temperature analysis each month. The flaw affected only 2000 and later,
and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few
thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to
some press reports, this did not change the rankings of global temperatures. Nor
did it change our rankings of the top few years in the U.S., with 1934 the warmest
in our record and 1998 practically tied with it. The claim in the news reports
that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see
in our 2001 paper, 1934 was the warmest in our record then, and it is now, with
and without the programming flaw. We also point out in that paper that the
differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intent of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the Washington Times (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the " U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century - 2000, 2002, 2003, 2004 - plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of <http://climateaudit.com/> climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even American: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings - albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

To: "James Hansen" <jhansen@giss.nasa.gov>, "Reto Ruedy" <rruedy@giss.nasa.gov>

I am sure I had 1998 warmer than 1934 at least once because on my own temperature web page (which most people never look at), I have

US annual

(Last Modified: 2007-01-12)

and since it was made in January when I updated all the graphs, I had my US mean table which is consistent with this until last Monday.

I didn't keep all the data, but some of them are

	1934	1998	
1999 July	1.459	0.918	
2000 Nov.	1.273	1.151	
2001 Jan.	1.235	1.199	<= These changes in early years may be due to different analysis
2006 Jan.	1.235	0.930	<= This is questionable, I may have kept some data which I was checking.
2007 Jan.	1.227	1.242	<= This is only time we had 1998 warmer than 1934, but one web for 7 months.
2007 Mar.	1.247	1.234	<= Somehow I recomputed in March, but didn't make changes to the web page.
2007 Aug.	1.249	1.226	<= Most recent with corrections, and with July data

I am sorry, I should have kept more data, but I was not interested in US data after 2001 paper.

Makiko

At 13:27 2007/08/14, James Hansen wrote:

Makiko, Reto, could you please clear this up. Other people keep saying the same thing that Demian does, i.e., that we previously claimed that 1998 was warmer than 1934. Is that right? I am quite sure that our 2001 paper shows 1934 slightly warmer, as we still find. Of course, scientifically this is all nonsense, as the difference of 0.02 is much less than the accuracy, so practically it should be stated as a tie. I know that whenever new stations are added to the record it can change things by small amounts. Did we once find 1998 as warmer??? Jim (I will be away from e-mail for a few hours).

Thanks, James. I'm not familiar with that paper from 2001. Is it not true, though, that NASA's rankings, as available at:

<http://data.giss.nasa.gov/gistemp/graphs/Fig.D.txt>

now show 1934 as the hottest year, where 1998 used to hold that position?

thanks,
demian

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Jim

On 8/14/07, DEMIAN MCLEAN, BLOOMBERG/ NEWSROOM: <<<mailto:dmclean8@bloomberg.net>>> wrote:

james, pardon me: i see the records volz was referring to are *global*. the u.s. figures showed 1998 as the warmest year. nevertheless, nasa has indeed newly ranked 1934 as the warmest year. also, i'd be grateful if you could respond to the second question, regarding your algorithm and making it public.

best,
demian

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intent of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the Washington Times (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the " U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century - 2000, 2002, 2003, 2004 - plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of <<http://climateaudit.com/>>climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even American: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings - albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website <http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html,>http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

I can't find the article in Washington Post which you just mentioned in this e-mail.

Makiko

On 8/15/07, James Hansen <jhansen@giss.nasa.gov> wrote:

I intend to finish writing a discussion today. Assuming that I succeed at that, if we can't make maps for the uncorrected data, we will get along without that. The Washington Post did a good job with their story -- good thing that I took their call. The Washington Times is a political rag. Jim

On 8/15/07, Makiko Sato <makis@giss.nasa.gov> wrote:

OK. As long as I can get wrong and corrected data in the same format from Reto, I can make these maps easily. As I showed on ~makis/GISSTemp, the corrected ones I get from Reto's web page and the ones I made map data using his old data look very different, and we cannot show them together.

First I thought any data are OK, but I am sure many will compare maps with our web site. So I know it is a lot of work for Reto as usual, but since it is getting more and more a serious problem (not scientifically at all but politically), I will ask him to put old data on a temporary web site so that I can get the map data using the old data from a web site in exactly the same manner as the new ones.

How soon do you need? I cannot come in Friday.

Makiko

On 8/15/07, James Hansen <jhansen@giss.nasa.gov> wrote:

I am now writing a new clear discussion of the whole matter (now that Congress and NASA management are involved). I would like the first figure

to be the two figures that you made before (line graph of global T and line

graph of U.S. T, showing the original and corrected results). These should

be side by side, and thus smaller than before.

The other figure should be maps. I am only interested in land+ocean.

By

the way I cannot understand your 1934 vs 1998 maps. As you seem to be able

to show three maps across very well, we might consider including 1934 and

1998 maps (land plus ocean in both cases). Here is the maps that I think we

would like:

Column 1 "1997-2006 relative to 1880-1920"

Column 2 "1997-2006 relative to 1951-1980"

Column 3 "1934 versus 1998"

Heading for 1st and 2nd maps in top row: Flawed Data

Heading for 3rd map in top row: 1934 relative to 1951-1980

Heading for 1st and 2nd maps in 2nd row: Corrected Data

Heading for 3rd map in 2nd row: 1998 relative to 1951-1980

On second thought, maybe it is better to make the 4 maps that go together as

a two-by-two figure, and then make a third figure with four parts 1934, 1998, and the two warmest U.S. years in 2000-2006.

On 8/14/07, Makiko Sato <makis@giss.nasa.gov> wrote:

I tried my best, but as I explained to you in the msg on your cell, I can't make exactly the same maps with/without corrections.

Subject: global maps of 1998-2006 annual mean temperatures
From: Makiko Sato <makis@giss.nasa.gov>
Date: Wed, 15 Aug 2007 12:45:52 -0400
To: "James Hansen" <jhansen@giss.nasa.gov>
CC: rruedy@giss.nasa.gov

Jim,

As we talked on the phone, I made global maps of 1998-2006 annual mean temperatures, with the US and global mean ranking among these years printed at the titles. (The 3rd set of maps from the top on [http://www.giss.nasa.gov/~makis/GISS Temp/](http://www.giss.nasa.gov/~makis/GISS_Temp/)) I don't know if it is a good idea to show only the US warmest in recent years because they may say we just picked up the years we like.

About the uncorrected data, Reto is going to make a utility to compute temperature anomalies exactly in the way he does on the web pages, and switch the data from newest to some old ones, so that I can make exactly in the same way for both corrected and uncorrected (and the same as the web). He said cut and paste US onto the global map is dangerous because US means are extended with 1200 km radius to Canada and Mexico. He thinks he can do it within a few hours.

Reto is also going to write you that unadjusting those hundred some stations didn't make almost any difference in the US mean and made very little difference in the global means.

Jim,

I read this. Since I I can't talk about the title or the tone you write, so I can tell only minor things.

(1) 1st sentence, you wrote "global temperature map", but do you want to say only about the map? Tables and a monthly graph are updated every month.

(2) in the second paragraph, you wrote "only after 2000". Strictly speaking, isn't it "only in 2000 and afterwards"?

(3) "XX July 2007" should be "August 7, 2007", I think. Isn't it, Reto?

Makiko

At 13:44 2007/08/15, James Hansen wrote:

Maybe you should read the first part of this story to make sure there are no errors.

Robert, if you get this e-mail: would you be available later today to put this story (to be in an e-mail) on the Columbia web site? Or can you give directions for someone else to do that?

Jim

The Real Deal: Usufruct & the Gorilla

Fox, Washington Times, and their like have gone bananas over a flaw discovered in the computer program that produces a global temperature map at GISS each month. They have even managed to get Congress and NASA Headquarters involved. Now we know what mom meant when she said "don't make a federal case out of it". Hey, what is really going on here?

The said computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001). The flaw affected temperatures only in the United States (by just over a tenth of a degree) and only after 2000. We made the adjustment to the program, thanked the fellow who pointed it out, and thought that was the end of it.

[The correction: As explained in the e-mail sent last week, one improvement made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the U.S. as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day of temperature measurements, etc. Our computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program instead picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this

introduced a discontinuity in temperature anomalies in 2000. This discontinuity can be removed by comparing USHC and GHCN records just before 2000, and this correction was made to the GISS computer program on XX July 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

Figure 1. Global (a) and U.S. (b) before and after correction of flaw in computer program.

What we have here is a case of dogged contrarians who present results in ways intended to deceive the public into believing that the changes have greater significance than reality. They aim to make a mountain out of a mole hill. I believe that these people are not stupid, instead they are seeking to create a brouhaha and muddy the waters in the climate change story. They seem to know exactly what they are doing and believe they can get away with it, because the public does not have the time, inclination, and training to discern what is a significant change with regard to the global warming issue.

The proclamations of the contrarians are a deceit, but their story raises a much more important matter, usufruct. It is the most important issue in the entire global warming story, in my opinion. The players in the present U.S. temperature story, we scientists included, are just bit players. The characters in the main drama are big fish, really big fish. But before we get to that crucial matter, I need to make clear how the deceit of the little fish works, to expose their sham.

Instead of showing the impact of the flaw in our analysis program via a graph such as Figure 1, as a scientist would do (and as would immediately reveal how significant the flaw was), they instead choose to discuss the ranking of temperature in different years. We have thus been besieged by journalists saying "they say that correcting your error caused the warmest year to become 1934 rather than a recent year, is that right!?"

Hardly. First of all, many journalists had the impression that they were talking about global temperature. As you can see from Figure 1a, global warming is unaffected by the flaw. This realization should be enough to make most journalists lose interest, as global warming refers to global temperature.

But what if you are a chauvinist and only care about temperature in the United States? Did correcting the flaw in the program change the time of calculated maximum temperature to 1934? No. If you look at our 2001 paper, and get out your micrometer, you will see that we found 1934 to be the warmest year in the United States, by a hair, of the order of 0.01°C warmer than 1998, the same as the result that we find now. Of course the difference in the 1934 and 1998 temperatures is not significant, and we made clear in our paper that such years have to be declared as being practically a dead-heat.

Indeed, when we receive new data each month, which often adds in new stations, or modifies the results at a small number of stations, the results for a given year can fluctuate as much as a few hundredths of a degree. Also the GISS ranking is commonly different than that obtained in the NOAA or British analyses. This is expected, as there are significant differences in the methods. For example, the urban warming that we estimate (and remove) is larger than that used by the other groups.

With suggested editing below, I believe that this should allow a complete version of the new front page to GISTEMP. I think that you should go ahead and replace it without waiting for me to get back from Denmark. Jim

On 9/15/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Jim,

In the description of step2 (homogeneization) "urban" should be replaced by "urban and peri-urban" or "non-rural" or we may add a sentence to indicate that "small-town" stations are adjusted the same way as urban stations. Although it is mentioned at the end of the previous section, it should probably be repeated here to avoid accusations of inconsistency.

let's use: "urban and peri-urban (i.e., other than rural)" that makes an unambiguous definition of our categories

April 2006 modification:

Looking at maps based on ocean data alone, we noticed that the HadISST data (1880-1981) extended to regions containing sea ice, whereas the NOAA data (1982-present) did not. In order to get a more consistent time series, the HadISST part was restricted to the same ice-free regions as the NOAA data. Since the temperature of water containing ice is always near the freezing point, including data from such regions tends to artificially dampen any heating or cooling trend.

April 2006 modification: HadISST ocean temperatures are now used only for regions that are identified as ice-free in both the NOAA and HadISST records. This change effects a small number of gridboxes in which HadISST has sea ice while NOAA has open water. The prior approach damped temperature change at these gridboxes because of specification of a fixed temperature in sea ice regions. The new approach still yields a conservative estimate of surface air temperature change, as surface air temperature usually changes markedly when sea ice is replaced by open water or vice versa. Because of the small area of these gridboxes the effect on global temperature change was negligible.

To: gs210@columbia.edu, rruedy@giss.nasa.gov

Yes, I knew about it. I thought 7 months out of 12 for the annual mean is dangerous, but 55 months out of 60 is quite safe, but since people may pick up any small things these days, I will remove it after I make all figures for Jim's write up -- before I home.

Makiko

At 15:00 2007/08/15, gs210@columbia.edu wrote:

One final quibble. In Fig A2, we now have the 5 year mean value for 2005 - which implies that 2007 data is being used in the calculation. But since 2007 isn't complete, that number will change by the end of the year. It might be cleaner not to calculate the that last value since it uses information that isn't seen (yet) in the annual average numbers.

Makiko

At 17:46 2007/08/16, you wrote:

Dear Dr. Posamentier,

As described in detail in the papers mentioned below, we did not try to think up any adjustments, but finessed the whole question as follows: We basically tweak the urban records so that they look exactly like their rural neighbors as far as the long term trend is concerned.

For each urban station, we compute a mean series based on all neighboring rural stations. If there are not enough rural stations near that urban station, we completely disregard the urban station. If the urban station is longer than the rural combination, the unsupported part of the urban station is dropped. Finally we find a best approximation to the difference between rural and urban series with a straight line or a line with a knee at a variable point and subtract that difference from the urban record.

For alternate approaches to this question, please contact USHCN. They employ a team of people working full time on observed data analysis. We are a modeling group and spend just enough time on observed temperature data to keep our temperature website up-to-date.

Dear Dr Sato

I fear you (NASA GISS) are getting very bad publicity here in the UK. I do not think Dr Hansen's rather flippant and aggressive response is helping. Why is his first response titled 'lights on upstairs'? Why is the second one 'Usufruct and the Gorilla'? What do these terms mean? Why does Dr Hansen adopt such a tone as 'The proclamations of the contrarians are a deceit'? This appears irrational, unscientific and unprofessional.

Jim,

Of course Reto thinks the ranking that shows which year was warmer by 0.01 deg is stupid. But as long as I give the table of US mean temperature on our web site, people can make rankings themselves. What Reto wanted to tell you was from Jan. 7 - Aug. 7, 2007, we had 1998 warmer than 1934 by 0.01 deg in the table I show on our web page.

(The reason was those numbers keep changing by such a small amount by adding station data, and probably as Reto pointed out, we processed data in January before a lot of data came in. These recent data can change numbers in old time by small amounts.) From next time I will update the US mean table every month. I was doing it only once a year because I didn't think people would make such a mess out of 0.01 deg difference in US. 0.01 deg is negligible globally but even 2% of that for the US!!

Makiko

On 8/24/07, James Hansen <jhansen@giss.nasa.gov> wrote:

Not sure that I understand this. It mentions 1934 and 1998 were tied for several months in our monthly updates, but later you say that 1998 was warmest (presumably by a meaningless 0.01, although I do not remember that - and why would we have cared or why would we have checked that)? In general I think that we want to avoid going into more and more detail about ranking of individual years. As far as I remember, we have always discouraged that as being somewhat nonsensical, other than the question of what is the warmest year, with uncertainty. Also I don't think that people, such as Gore, are being unreasonable when they make statements such as (about) 9 of 10 warmest years were in the past two decades, or however they say that -- but this of course refers to global temperature, which is much less noisy and more relevant to the question of human-made climate change. The contrarians are cleverly mixing up these two matters, global and U.S., thus completely confusing the public discussion, and again winning more time in their attempt to keep things confused, not without aid from their unwitting ally, the media. As I tried to make clear in 'Usufruct', that is the real battle, as we are running out of time. They will live in infamy, but they either do not understand or they don't give a damn. Jim

On 8/23/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Jim,

I don't know whether Andrew Revkin is interested in the details below:

The US temperature graph in our 1999 paper, based on GHCN data, shows 1934 0.5C warmer than 1998; 1998 was in 5th place behind 1921, 1931, 1938, 1953.

In the corresponding graph in our 2001 paper, now based on the carefully corrected USHCN data, 1934 and 1998 are in first, 1921 in third place (NOAA who provided the USHCN data had 1998 slightly ahead of 1934).

The US table we had posted during all of 2006 showed 1998 and 1934 even at 1.24C. (I got a copy from a journalist in Brazil, we don't save these

data).

As far as I know, the US table on our site from Jan to Aug 2007 was the first and only one with 1998 ahead of 1934 - some US stations must have still been missing in the GHCN file we downloaded on January 8, 2007. (Each month, GHCN regenerates the whole file over a period of a few days; in previous years we had to wait til mid January for the US stations to be added in again).

Reto

On Thu, 2007-08-23 at 20:51 +0200, James Hansen wrote:

We can add an uncertainty, indeed we already include a bar at several points on our temperature curve, but we note that it only includes the largest source of uncertainty in the temperature change (incomplete spatial coverage).

As far as I know we do not make such a list. We don't like such lists, because the results are not significant and are certain to differ from one group to another. It is generally the media that makes a list. We look for a new record high, but note that it is a virtual tie if the difference is small.

Just look at our published paper. It has 1934 as the warmest year, by an insignificant amount, with 1998 second. The same result that we have now. This ranking was not affected by the flaw in post 2000 data.

Of course it is good to improve the station data. Temperature is an absolute measurement, however, so errors over time are not cumulative. When there are several thousand stations it is easy to find what seem like a huge number of stations with problems.

Jim

On 8/23/07, Andrew Revkin <anrevk@nytimes.com> wrote:

noaa folks are saying they're working on adding a description of uncertainty levels to year-to-year temp time series. and lawrimore says they could do better in press outreach to stress this.

do you agree that this should be more clearly communicated... should GISS or NOAA or others even try to make a list of individual years as sharp data points?

separately, i'm still a bit confused about whether GISS ever had 1934 as hottest 48-state year or not. can you help clarify?

finally, do you agree that generally we (globally) should be doing a lot more to improve surface temperature tracking? i never, til today, visited www.surfacestations.org and found it quite amazing. if our stations are that shoddy, what's it like in Mongolia?

Reto Ruedy < rruedy@giss.nasa.gov >

Subject: Re: Fwd: alt.cleaning

From: Makiko Sato <makis@giss.nasa.gov>

Date: Tue, 21 Aug 2007 16:42:53 -0400

To: rruedy@giss.nasa.gov, James Hansen <jhansen@giss.nasa.gov>

Since Reto made maps already, I thought there is nothing I can do, but I made a simple set of 2x4 maps on [http://www.giss.nasa.gov/~makis/GISS Temp/](http://www.giss.nasa.gov/~makis/GISS_Temp/).

Makiko

At 12:28 2007/08/21, Reto Ruedy wrote:

Jim and Makiko,

As Makiko assumed, I had already made all those maps (on /climl/Steve/alternate_cleaning/.), but I did not instantly tell you, since I was a little puzzled at first at the outcome.

The LOTI-trends were unaffected for both periods: the 1880-2006 change was .69 C, the 1900-2006 change was .65 C for all 3 cases.

The Ts-trends decreased from .88 C to .84 C, and .72 C to .69 C; the puzzling fact was that "no cleaning" and "adjust St.Helena and Lihue only" gave the same result. Whereas the trend for Lihue was decreased by our adjustment as expected (in both cases we raised the early part of the series), the St.Helena trend surprisingly increased and the 2 effects canceled each other out.

The solution of the St.Helena puzzle is:

For Lihue, GHCN lists 1 long series 1905-2007 with very few missing months (and a few extra short series), i.e. the long series passed GHCN's quality control and our change had the expected effect.

This was not the case for St.Helena (16S,6W); there GHCN lists 2 series. The first one ends before the move, the 2nd starts after the move. Our fix glued the 2 pieces together with a proper adjustment.

Without that fix, the "glueing" is done by the "neighbors"; the closest (Wide Awake Fi at 8S,14W, 1300km) consists of 3 pieces. The long one goes from 1923-May1976, with few gaps up to 1972, 1973-6 have 6-8 months missing. A 2nd source 1971-1980 agrees with source 1 in 1971-2, is missing most of 1973-1974, some of 1975 and has complete, but atypically low data for 1976-1980, at which point it ends. The 3rd piece 1991-2007 is more in line with piece 1 but has many years missing - so it probably was not used due to lacking a sufficient overlap with other stations.

The only other station with a substantial overlap with both St.Helena pieces is Tabou (4N,7W, 2200 km) which happens to have an unusual dip in the mid-70s of a totally different nature than Wide Awake.

Quarter-Degree Fix Fuels Climate Fight

By <http://topics.nytimes.com/top/reference/timestopics/people/r/andrew_c_revkin/index.html?inline=nyt-per>ANDREW C. REVKIN

Never underestimate the power of the blogosphere and a quarter of a degree to inflame the fight over <<http://topics.nytimes.com/top/news/science/topics/globalwarming/index.html?inline=nyt-classifier>>global warming.

A quarter-degree Fahrenheit is roughly the downward adjustment <http://topics.nytimes.com/top/reference/timestopics/organizations/n/national_aeronautics_and_space_administration/index.html?inline=nyt-org>NASA scientists made earlier this month in their annual estimates of the average temperature in the contiguous 48 states since 2000. They corrected the numbers after an error in meshing two sets of temperature data was discovered by <<http://www.climateaudit.org>>Stephen McIntyre, a blogger and retired business executive in Toronto. Smaller adjustments were made to some readings for some preceding years.

All of this would most likely have passed unremarkably if Mr. McIntyre had not blogged that the adjustments changed the rankings of warmest years for the contiguous states since 1895, when record-keeping began.

Suddenly, 1934 appeared to vault ahead of 1998 as the warmest year on record (by a statistically meaningless 0.036 degrees Fahrenheit). In NASA's most recent data set,

1934 had followed 1998 by a statistically meaningless 0.018 degrees. Conservative bloggers, columnists and radio hosts pounced. "We have proof of man-made global warming," http://topics.nytimes.com/top/reference/timestopics/people/1/rush_limbaugh/index.html?inline=nyt-per>Rush Limbaughtold his radio audience. "The man-made global warming is inside NASA."

Mr. McIntyre, who has spent years seeking flaws in studies pointing to human-driven climate change, traded broadsides on the Web with <http://www.columbia.edu/~jehl>>James E. Hansen, the NASA team's leader. Dr. Hansen said he would not "joust with court jesters" and Mr. McIntyre posited that Dr. Hansen might have a "Jor-El complex" a reference to Superman's father, who foresaw the destruction of his planet and sent his son packing.

Blogs are still reverberating, but Mr. McIntyre, Dr. Hansen and others familiar with the initial data revisions are clarifying what is, and is not, at issue.

One thing not in question, Mr. McIntyre and Dr. Hansen agree, is the merit of shifting away from energy choices that contribute heat-trapping greenhouse gases to the atmosphere.

Mr. McIntyre said he feels "climate change is a serious issue." His personal preference is to shift increasingly to nuclear power and away from coal and oil, the main source of heat-trapping carbon dioxide.

Mr. McIntyre and Dr. Hansen also agree that the NASA data glitch had no effect on the global temperature trend, nudging it by an insignificant thousandth of a degree.

Everyone appears also to agree that too much attention is paid to records, particularly given that the difference between 1934, 1998, and several other sets of years in the top 10 warmest list for the United States are so small as to be statistically meaningless.

Mr. McIntyre said that when he posted the revised list under the heading "A New Leaderboard at the U.S. Open," "I just was sort of having some fun with it as much as anything."

He added: "The significance of things has been misstated by Limbaugh and people like that."

Dr. Hansen and his team note that they rarely, if ever, discuss individual years, particularly regional findings like those for the United States (the lower 48 are only 2 percent of the planet's surface). "In general I think that we want to avoid going into more and more detail about ranking of individual years," he said in an e-mail message. "As far as I remember, we have always discouraged that as being somewhat nonsensical."

Jay Lawrimore, a scientist at the <http://www.ncdc.noaa.gov>>National Climatic Data Center of the Commerce Department who works on assembling the climate records that NASA analyzed, said his agency could probably do a better job of emphasizing the uncertainty surrounding its annual temperature announcements.

Indeed, there is enough wiggle room in the numbers that the center has a different list of the 10 warmest years than those produced using NASA's and Mr. McIntyre's analyses. By the climate center's reckoning, 1998 remains the warmest year for the 48 states (with 2006 second and 1934 third).

Dr. Lawrimore, Dr. Hansen and other experts said that trends are far more important than particular years, and the recent widespread warming trend has been clear and very distinct from the regional hot spell that drove up United States temperatures in the 1930s.

Mr. McIntyre and the government scientists do agree on at least one more thing: the need to improve the quality of climate data gathered around the world, including in

the United States, which has by far the planet's biggest network of meteorological stations.

Mr. McIntyre is not alone in pointing out that the need to adjust and revise such data with the attendant risk of mistakes would be reduced with more care and consistency taken in collecting climate data.

The http://topics.nytimes.com/top/reference/timestopics/organizations/n/national_academy_of_sciences/index.html?inline=nyt-org National Academy of Sciences has repeatedly called for improvements in climate monitoring. An independent group of meteorologists and weather buffs is compiling its own gallery of American weather stations at <http://www.surfacestations.org>, with photographs showing glaring problems, like thermometers placed next to asphalt runways and parking lots.

Dr. Lawrimore said that the government is preparing to build a <http://www.ncdc.noaa.gov/crn> climate reference network of more sophisticated, and consistent, monitoring stations that should cut uncertainty in gauging future trends.

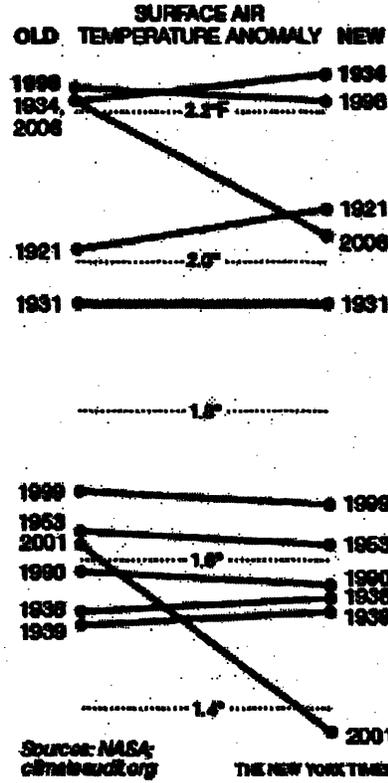

In any case, he said, the evidence for human-driven warming remains robust. "Saying what they're saying has just provided an opportunity for them to create doubt in people's minds," he said of the bloggers.

Thank you, Reto.

Makiko

No - but I needed an extra digit to decide that question (1.244 vs 1.238C). Maybe, we'll switch to a single digit in the US-table, then we have 3 years in the number 1 position.

I should have looked at the graphs and maps I myself made for the Gorilla <http://www.columbia.edu/~jeh1/realdeal.16aug20074.pdf>.

Makiko

On 8/27/07, James Hansen <jhansen@giss.nasa.gov> wrote:

Yes, I should make clear what I meant. I know that if you take the linear trend the U.S. temperature change is less than the global trend. But if you compare the mean for the past 10 years to the mean for either 1880-1900 or 1880-1920, the warming is about 1.0C (1.8F) for the U.S. and 0.8C for the global mean. Ten years is enough to pretty well average out the large year-to-year fluctuations, so I think it is a fair way to look at the magnitude of the warming. In a case where you have a large change near the end of the record the linear trend is not a very good way to look at the magnitude of the change. Jim

Note also, although the year to year fluctuations are large for an area the size of the contiguous states, the long-term (century scale) warming has been as large for the U.S. as for the global mean (actually a bit larger).

Jim Hansen

Jim,

Fig 1: Global map

The global trend is 0.65 (and 0.64 for 1906-2006), and the US averages yellow, which means about 0.35, almost half of the globe, but why did you write as above?

Jim,

Before you come in to talk with Reto about this person, I want to show you the web pages and the graph Reto showed me this crazy one made.

[http://www.stikir.com/index.php/Welcome to Stikir%21](http://www.stikir.com/index.php/Welcome%20to%20Stikir%21)

[http://www.stikir.com/index.php/Top down Analysis of GHCN climate data](http://www.stikir.com/index.php/Top%20down%20Analysis%20of%20GHCN%20climate%20data)

with

Global annual average temperature, all factors ignored

Here's a chart of the average annual temperature from the data set. Trend inferences could be made from this plot if one supposed that all factor effects were negated by the random sampling.

Emacs!

The chart indicates that measurements recorded in this dataset in the late 20th century were, on average 6-7 deg C hotter than those recorded in the 1700s. The following analyses explore the dataset with the goal of identifying those factors that have the largest contribution to the temporal differences observed in average temperature levels.

I don't think you should think about him seriously.

Robert,

Jim came to my office and said, "Let's go to see Reto", and three of us talked about it a little. Jim wants Reto to put the temperature program on the web, Reto says he is converting Jay's program to FORTRAN and he should do some checks also. Jim wants to write something more clearly once more after Reto puts the computer program on the web. He is sending out something about Pushker's stuff to his e-mail list and as a foot note he will write a little about temperature -- about the difference between with and without cleaning results, which I think is nothing to do with McIntyre because McI doesn't know about cleaning.

Something like that. Right, Reto? If you want to know more in detail, please ask Reto.

Dear Dr. Hansen,

Thank you very much for your quick reply. I look forward to seeing the code.

As it happens, I frequently use Python (in particular, the SciPy and Numeric Python packages) in my own data analysis projects. I think it is one of the best available programming environments for data processing, and I would heartily recommend it. Much of it is very similar to Matlab, which you may be more familiar with.

Best regards,

On 9/4/07, James Hansen <jhansen@giss.nasa.gov> wrote:

You are welcome to have a copy of our computer code. Depending upon your programming background, there is a possible small complication in that parts of the computer program as it is used were written by a person (Jay Glascoe) who left several years ago in a code (Python) that is obscure to most of us (perhaps all of us at GISS). Reto Ruedy is in the process of rewriting that part in Fortran, as we know the function of it; and the Python and Fortran codes should give the same results. In the interim, we will release the codes as they have been used (including Jay's Python subroutines). The procedure to access the codes will be described in my next e-mail, which I will send this week.

Jim Hansen

(By the way, Reto also notes that the codes are a collection that accumulated over 25 years. Actually, I started with an NYU undergraduate student in the 1970s, but Sergej Lededeff replaced most of that code in the early 1980s. Reto says that he intends to simplify/combine steps in the code, but it may be several weeks before he can do that.)

Jim,

I understand the need to make the programs and input files available. But to put out an unusable product (though it works on our machines, based on the directory structures, compilers, etc. of the various machines) that has to be repeatedly changed may be counterproductive. I wish I had another week - or at least a weekend where I could work without interruption.

(1) As far as list of stations we remove is concerned, most are removed or remain unused automatically because their records are too short to have sufficient overlap with the dominating stations. Do you only want a list of those stations that are explicitly removed at the beginning of the process due to their strange data ?

(2) Corrections: We correct 2 stations (St.Helena and Lihue) and use USHCN instead of the corresponding GHCN data. The rest is dropping parts or all of a record (=cleaning). Hence:

"no corrections"="not correcting the 2 stations, not using USHCN, no cleaning",

"current"="2 corrections+USHCN+cleaning",

"no cleaning"="2 corrections+USHCN".

Are any 2 of these 3 options what you need ?

I guess (3) can be done by Makiko, if not let me know.

I can't open your attachment, but right now I am busy with something else, so I will ask you tomorrow. I am wondering if Jim can open it.

Makiko

At 15:44 2007/09/06, Reto Ruedy wrote:

Jim,

I prepared a documentation file (preliminary version attached) that divides the process into a preliminary and another 5 steps - Jay's programs are in step 1 and Robert is working on it (he has trouble compiling one of the C programs; also the order in which stations are combined seems dependent on the release of the data base system); I'm currently working on step 2 and Ken is working backwards from step 6 - hope to get through by tomorrow and combine it into a semi-coherent package.

A week seems a reasonable estimate to clean up what was missed - a total rewrite of Jay's programs however might easily take longer.

GISS Temperature Analysis

History

GISS started in the 1970s to use 1-D models to study climate forcings and their potential impact. These studies were continued using the GISS 3-D climate model.

However, comparisons with observed data were not easily possible, because long term temperature records (1880-present) are missing for large parts of the world and estimates for the global trends were not available in the literature.

GISS started to compute such estimates on the basis of the available data using MCDW reports and NOAA near real-time data. GISS established that useful estimates can be obtained for the global temperature changes during the past century with a careful investigation of the margin of error of such estimates.

Fortunately, the labor-intensive effort of collecting reports from various sources and of evaluating and cleaning those reports was taken over by a team of experts at NOAA (GHCN/USHCN).

GISS now concentrates on converting these data to anomalies and combining them into a gridded data set to get time series of large regional and global means.

Sources

Basic data set: GHCN - <ftp://ftp.ncdc.noaa.gov/pub/data/ghcn/v2>
v2.mean.Z (data file)
v2.temperature.inv.Z (station information file)

For Hohenpeissenberg -
http://members.lycos.nl/ErrenWijlens/co2/t_hohenpeissenberg_200306.txt
complete record for this rural station
(thanks to Hans Erren who reported it to GISS on
July 16, 2003)

For US: USHCN - http://cdiac.ornl.gov/ftp/ushcn_monthly
hcn_doe_mean_data.Z
station_inventory

For Antarctica: SCAR -
<http://www.antarctica.ac.uk/met/READER/surface/stationpt.html>

<http://www.antarctica.ac.uk/met/READER/temperature.html>

<http://www.antarctica.ac.uk/met/READER/aws/awspt.html>

SCAR contains some stations that are not part of GHCN - only those data are used

that are marked by SCAR as final

USHCN are a subset of GHCN, but those data were adjusted for various recording and protocol errors and discontinuities; this set is particularly relevant if studies of US temperatures are made. These corrections, obviously, contribute little to the GLOBAL temperature trend (since the data for the remaining 98% of the world are not as carefully investigated)

Step 0 : Merging of sources (do_comb_step0.sh)

GHCN contains reports from several sources, so there often are multiple records for the same location. Occasionally, a single record was divided up by NOAA into several pieces, e.g. if suspicious discontinuities were discovered.

USHCN and SCAR contain single source reports but in different formats/units and with different or no identification numbers. For USHCN, the table "ushcn.tbl" gives a translation key, for SCAR we extended the WMO number if it existed or created a new ID if it did not (2 cases). SCAR stations are treated as new sources.

Adding SCAR data to GHCN:

The tables were reformatted and the data rescaled to fit the GHCN format; the new stations were added to the inventory file. The site temperature.html has not been updated for over a year; we found and corrected a few typos in that file.

Replacing USHCN-unmodified by USHCN-corrected data:

The reports were converted from F to C and reformatted; data marked as being filled in using interpolation were removed. USHCN-IDs were replaced by the corresponding GHCN-ID. The latest common 15 years for each station were used to compare corrected and uncorrected data. The offset obtained in that way was subtracted from the corrected USHCN reports to match any new incoming GHCN reports for that station (GHCN reports are updated monthly, in the past, USHCN data lagged by 2-5 years).

Filling in missing data for Hohenpeissenberg:

This is a version of a GHCN report with missing data filled in, so it is used to fill the gaps of the corresponding GHCN series.

Result: v2.meanz

Step 1 : Simplifications, elimination of dubious records, 2 adjustments
(do_comb_step1.sh)

The various sources at a single location are combined into one record, if possible, using a method similar to the reference station method. The shift is determined in this case on series of estimated annual means.

Non-overlapping records are viewed as a single record, unless this would result introducing a discontinuity; in the documented case of St.Helena the discontinuity is eliminated by adding 1C to the early part.

Some unphysical looking segments were eliminated after manual inspection of unusual looking annual mean graphs and comparing them to the corresponding graphs of all neighboring stations. (As a test, the analysis was done including all these parts - the global mean series was not affected)

After noticing an unusual warming trend in Hawaii, closer investigation showed its origin to be in the Lihue record; it had a discontinuity around 1950 not present in any neighboring station. Based on those data, we added 0.8C to the part before the discontinuity.

Step 2 : Splitting into zonal sections and homogeneization
(do_comb_step2.sh)

Since the gridding program was written about 30 years ago for what now would be viewed as tiny machines, the data were divided into 6 zonal sections. We plan to reprogram the gridding and analysis section of our procedure to eliminate this division.

The goal of the homogeneization effort is to avoid any impact (warming or cooling) of the changing environment that some stations experienced by changing the global trend of any non-rural station to match the global trend of their rural neighbors. If no such neighbors exist, the station is completely dropped, if the rural records are shorter, part of the non-rural record is dropped.

Step 3 : Gridding and computation of zonal means (do_comb_step3.sh)

A grid of 8000 grid boxes of equal area is used. Time series are changed to series of anomalies. For each grid box, the stations within that grid box and also any station within 1200km of the center of that box are combined using the reference station method.

A similar method is also used to find a series of anomalies for 80 regions consisting of 100 boxes from the series for those boxes, and again to find the series for 6 latitudinal zones from those regional series, and finally to find the hemispheric and global series from the zonal series.

It should be noted that the base period for any of these anomalies is not necessarily the same for each grid box, region, zone. This is irrelevant when computing maps of trends; however, when used to compute anomalies, we always have to subtract the base period series from the series of the selected time period to get the proper anomaly map.

Step 4 : Regrid sea surface temperature anomalies

Sources: <http://www.hadobs.org> HadISST1: 1870-present
<ftp.emc.ncep.noaa.gov> cmb/sst/oimonth_v2 Reynolds 11/1981-present

For both sources, we compute the anomalies with respect to 1982-1991, use the Hadley data for the period 1880-11/1981 and Reynolds data for 12/1981-present.

These data are replicated on the 8000-box equal-area grid in order to be able to use the same utilities for surface and ocean data. Areas covered by sea ice are masked out (a fixed mask is used for all times).

Step 5 : Computation of LOTI zonal means

The same method as in step3 is used, except that for a particular grid box the anomaly or trend is computed twice, first based on surface data, then based on ocean data. Depending on the location of the grid box, one or the other is used with priority given to the surface data, if available.

Jim,

Now your seminar is over, let's concentrate on this temperature stuff. It's not clear to me exactly what I should do, but Reto may know. Do you want to talk to us before I start making maps? Or do you want me to go ahead with Reto?

Makiko

(3) maps showing the results with and without our changes -- the four maps that you made for 1880-2006 are fine, but the maps need to be made with Makiko's program/color scale etc. Also I would like to add two maps: delete the two maps on the left (which show the effect of St Helena/Lihue) and add the result when South America and Africa are replace with no data, the objective being to see how these continents contribute to the global mean temperature change. Clearly the data in those continents is pretty lousy, but how much difference does that make for the global mean?

A second objective is to show that the admittedly large problems with African and South American data does not significantly alter the inferred global warming (this second objective just requires Makiko to omit those areas).

"Peak Oil" Paper Revised and Temperature Analysis Code

To be removed from Jim Hansen's e-mail distribution respond with REMOVE in subject line.

(1) The paper "Implications of 'Peak Oil' for Atmospheric CO₂ and Climate", recently revised and resubmitted to *Environmental Research Letters*, is available at XXXXXXXXXXXX.

A principal concern of both referees was our use of a pulse-response function, fit to the Bern carbon cycle model, as opposed to a detailed carbon cycle model. We have clarified limitations of a pulse-response function, but frankly we consider the simplicity and transparency of this approach to be a merit, not a fault. We are concerned mainly with scenarios that have a chance of avoiding "dangerous" CO₂ levels, in which case the strong positive feedbacks found in some climate-carbon models are less likely, and in any case such feedbacks only add to the dichotomy between scenarios with declining emissions and "business-as-usual" scenarios.

We have minimized reference to a "dangerous" atmospheric CO₂ level to satisfy one of the referees. We retained one reference to our recent papers, which are published in peer-reviewed journals and, we believe, make a strong case that we are already close to a dangerous CO₂ level.

The principal conclusion of this paper is that it is possible to keep atmospheric CO₂ at a much lower limit than commonly assumed, provided that coal use is phased out except where the CO₂ is captured and stored, and use of unconventional fossil fuels is also accompanied by CO₂ capture and storage. This paper provides some of the rationale for the discussion in "Old King Coal II".

(2) Temperature Analysis Code

Reto Ruedy has organized into a single document as well as practical on a short time scale the programs that produce our global temperature analysis from publicly available data streams of temperature measurements. These are a combination of subroutines written over the past few decades by Sergej Lebedeff, Jay Glascoe, and Reto. Because the programs include a variety of languages and computer unique functions Reto would have preferred to have a week or two to combine these into a simpler more transparent structure, but because of a recent flood of demands for the programs, they are being made available as is. People interested in science may want to wait a week or two for a simplified version.

[Why not wait a week before sending this out? Lack of instant response to a request, even lack of a response in negative time, seems to be sufficient reason for international announcements. Steve McClintock stated on a radio program on September XX that GISS refused to give him our computer program. We have a series of e-mails between him and Reto showing that the request came the following day. The objectives here do not seem to be science.]

An introduction to the program description defines the scientific purposes. We have also made a few graphs that may help clarify the significance (or lack thereof) of criticisms in the blogosphere. The one aspect of our procedure where subjectivity could come into play is the

choice of which stations are eliminated from the record. This is based on identifying the (small fraction of) stations that raise a red flag (e.g., deviation of 5 standard deviations or more, or a large temporal discontinuity, as defined in our papers). The records of these stations were compared with records of the nearest neighboring stations; if neighboring stations displayed similar features the records were retained. We provide here the list of stations eliminated.

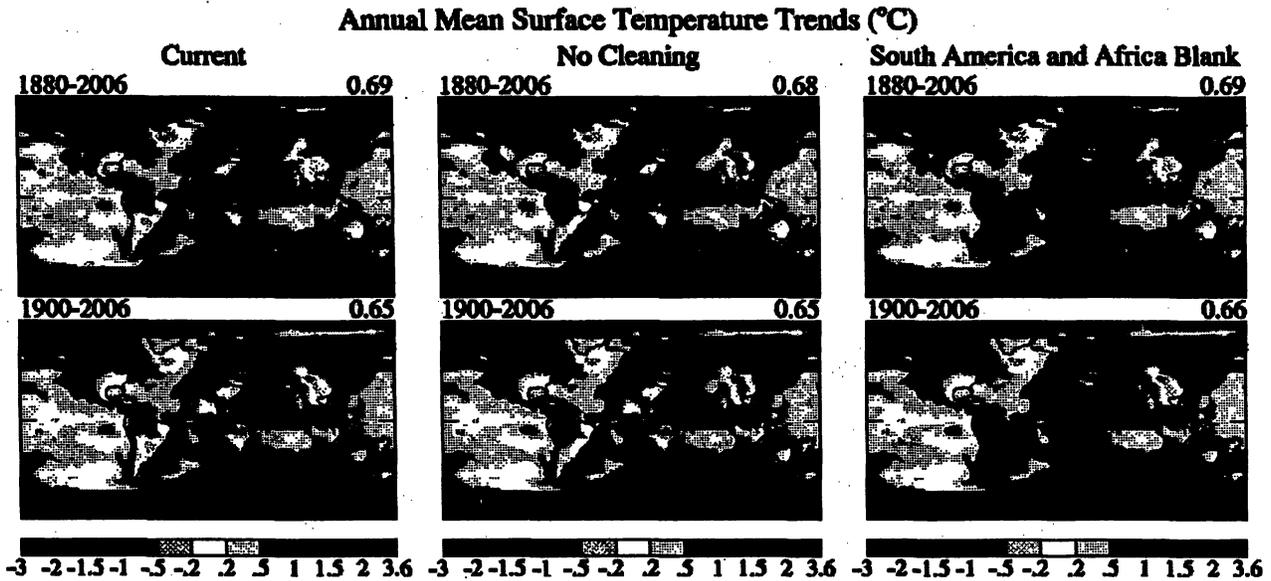

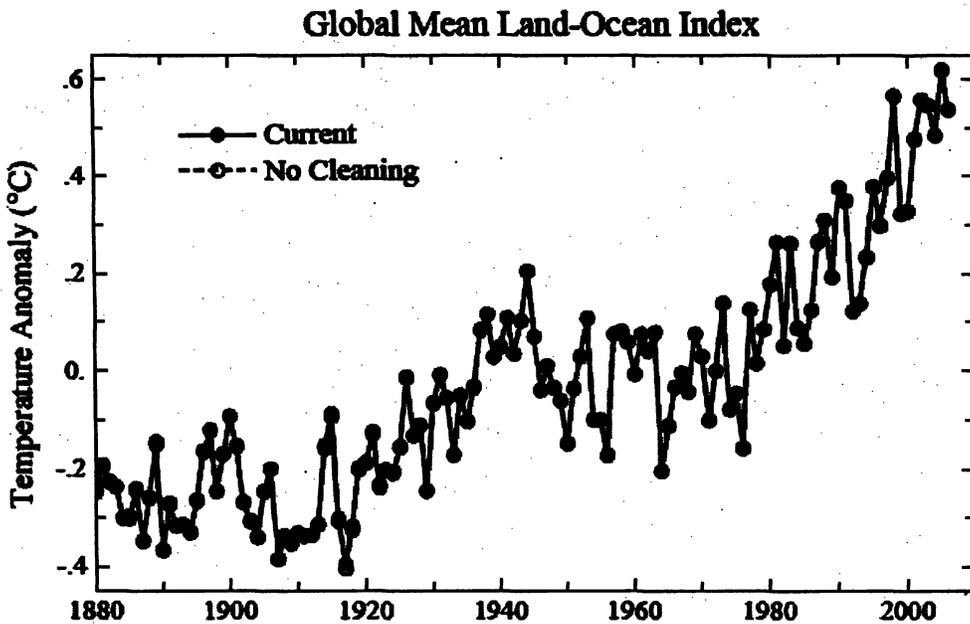

Figure 1 shows maps of the 1880-2006 and 1900-2006 changes of global temperature with and without these stations, and Figure 2 shows the global mean temperature with and without these stations. The effect is practically imperceptible and clearly insignificant.

Another favorite target of those who would raise doubt about the reality of global warming is the lack of quality data from South America and Africa, a legitimate concern. You will note in our maps of temperature change some blotches in South America and Africa, which are probably due to bad data. Our procedure does not throw out data because it looks unrealistic, as that would be subjective. But what is the global significance of these regions of exceptionally poor data? As shown by Figure 1, omission of South America and Africa has only a tiny effect on the global temperature change. Indeed, the difference that omitting these areas makes is to increase the global temperature change by (an entirely insignificant) 0.01C.

This is all the time that I intend to give to this subject, but in case you wonder why we subject ourselves to the shenanigans, there are scientific reasons, repeated here from the "history" introduction to the program description.

GISS Temperature Analysis

History

The basic GISS temperature analysis scheme was defined in the late 1970s by Jim Hansen when a method of estimating global temperature change was needed for comparison with one-dimensional global climate models. Prior temperature analyses, most notably those of Murray Mitchell, covered only 20-90N latitudes. Our rationale was that the number of Southern Hemisphere stations was sufficient for a meaningful estimate of global temperature change, because temperature anomalies and trends are highly correlated over substantial geographical distances. Our first published results (Hansen et al., Climate impact of increasing atmospheric carbon dioxide, *Science* 213, 957, 1981) showed that, contrary to impressions from northern latitudes, global cooling after 1940 was small, and there was net global warming of about 0.4C between the 1880s and 1970s.

Hansen and Lebedeff (Global trends of measured surface air temperature, *J. Geophys. Res.* 92, 13345, 1987) documented the analysis method, showing that the correlation of temperature change was reasonably strong for stations separated by up to 1200 km, especially at middle and high latitudes. They obtained quantitative estimates of the error in annual and 5-year mean temperature change by sampling at station locations a spatially complete data set of a long run of a global climate model, which was shown to have realistic spatial and temporal variability.

This derived error bar only addressed the error due to incomplete spatial coverage of measurements. As there are other potential sources of error, such as urban warming near meteorological stations, etc., many other methods have been used to verify the approximate magnitude of inferred global warming. These methods include inference of surface temperature change from vertical temperature profiles in the ground (bore holes) at many sites around the world, rate of glacier retreat at many locations, and studies by several groups of the effect of urban and other local human influences on the global temperature record. All of these yield consistent estimates of the approximate magnitude of global warming, which has now increased to about twice the magnitude that we reported in 1981. Still further affirmation of the reality of the warming is its spatial distribution, which shows largest values at locations remote from any local human influence, with a global pattern consistent with that expected for response to global climate forcings (larger in the Northern Hemisphere than the Southern Hemisphere, larger at high latitudes than low latitudes, larger over land than over ocean).

Some improvements in our analysis were made several years ago (*J. Geophys. Res.* **104**, 30997, 1999; **106**, 23947, 2001) including use of satellite-observed night lights to determine which stations in the United States are located in urban and peri-urban areas, the long-term trends of those stations being adjusted to agree with long-term trends of nearby rural stations.

[As you will see in the latter paper we found 1934 and 1998 to be in a statistical tie for warmest U.S. year, 1934 being warmer by an insignificant couple hundredths of a degree. We still find that result. The minor flaw recently found in our data analysis, which affected U.S. temperatures by 0.15C after 2000, did not alter this result. Pundits picking up on this non-story did not get this right, and further they tried to leave the impression that they were talking about global temperature. Ah me.]

You may wonder why we bother to put up with this hassle and the nasty e-mails that it brings. Well, there are at least a couple of good reasons.

First, there is scientific value in having near-real-time global temperature analyses, it is fairly easy to run the analyses as new data comes in each month, and a lot of people tell us that our analysis and presentation is useful to them. There is merit in having more than one group do the analyses because the results differ somewhat. For example, in 2005 we were the only group initially reporting that as being, on global mean, the warmest year in the record. We would not have obtained that result with our method of extrapolating estimates of anomalies out to distances of 1200 km from the nearest station. Later checks with satellite infrared data indicated that our Arctic and Greenland anomalies were, if anything, conservative.

“Peak Oil” Paper Revised and Temperature Analysis Code

To be removed from Jim Hansen’s e-mail distribution respond with REMOVE in subject line.

(1) The paper “Implications of ‘Peak Oil’ for Atmospheric CO₂ and Climate”, recently revised and resubmitted to *Environmental Research Letters*, is available at XXXXXXXXXXXXX.

A principal concern of both referees was our use of a pulse-response function, fit to the Bern carbon cycle model, as opposed to a detailed carbon cycle model. We have clarified limitations of a pulse-response function, but frankly we consider the simplicity and transparency of this approach to be a merit, not a fault. We are concerned mainly with scenarios that have a chance of avoiding “dangerous” CO₂ levels, in which case the strong positive feedbacks found in some climate-carbon models are less likely, and in any case such feedbacks only add to the dichotomy between scenarios with declining emissions and “business-as-usual” scenarios.

We have minimized reference to a “dangerous” atmospheric CO₂ level to satisfy one of the referees. We retained one reference to our recent papers, which are published in peer-reviewed journals and, we believe, make a strong case that we are already close to a dangerous CO₂ level.

The principal conclusion of this paper is that it is possible to keep atmospheric CO₂ at a much lower limit than commonly assumed, provided that coal use is phased out except where the CO₂ is captured and stored, and use of unconventional fossil fuels is also accompanied by CO₂ capture and storage. This paper provides some of the rationale for the discussion in “Old King Coal II”.

(2) Temperature Analysis Code

Reto Ruedy has organized into a single document as well as practical on a short time scale the programs that produce our global temperature analysis from publicly available data streams of temperature measurements. These are a combination of subroutines written over the past few decades by Sergej Lebedeff, Jay Glascoe, and Reto. Because the programs include a variety of languages and computer unique functions Reto would have preferred to have a week or two to combine these into a simpler more transparent structure, but because of a recent flood of demands for the programs, they are being made available as is. People interested in science may want to wait a week or two for a simplified version.

[Why not wait a week before sending this out? Lack of instant response to a request, even lack of a response in negative time, seems to be sufficient reason for international announcements. Steve McClintock stated on a radio program on September XX that GISS refused to give him our computer program. We have a series of e-mails between him and Reto showing that the request came the following day. The objectives here do not seem to be science.]

An introduction to the program description defines the scientific purposes. We have also made a few graphs that may help clarify the significance (or lack thereof) of criticisms in the blogosphere. The one aspect of our procedure where subjectivity could come into play is the

choice of which stations are eliminated from the record. This is based on identifying the (small fraction of) stations that raise a red flag (e.g., deviation of 5 standard deviations or more, or a large temporal discontinuity, as defined in our papers). The records of these stations were compared with records of the nearest neighboring stations; if neighboring stations displayed similar features the records were retained. We provide here the list of stations eliminated.

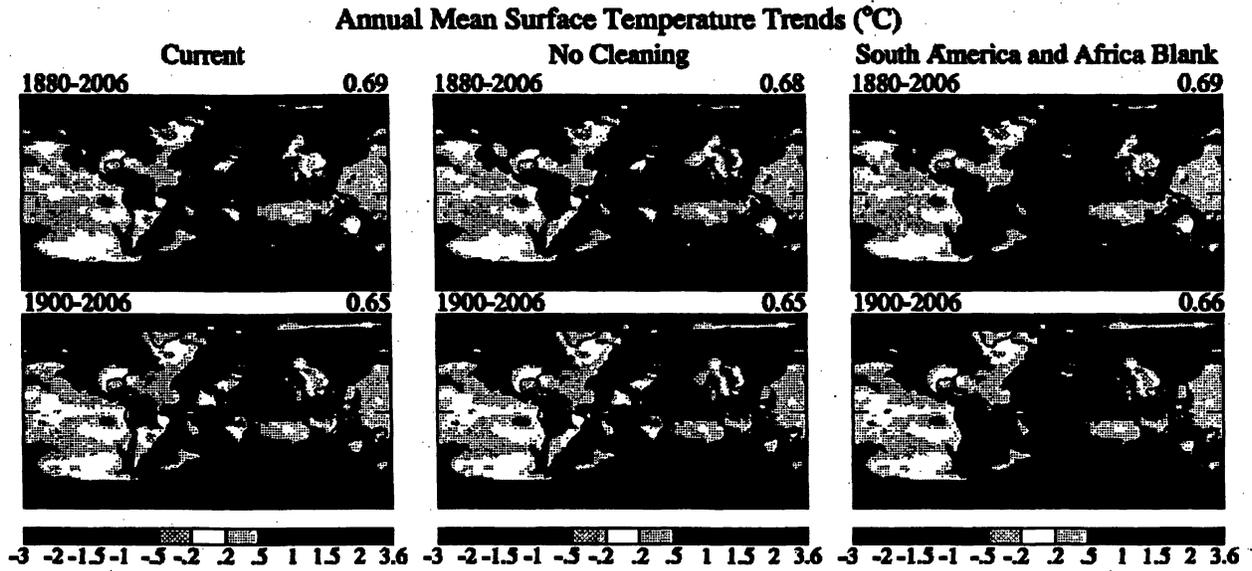

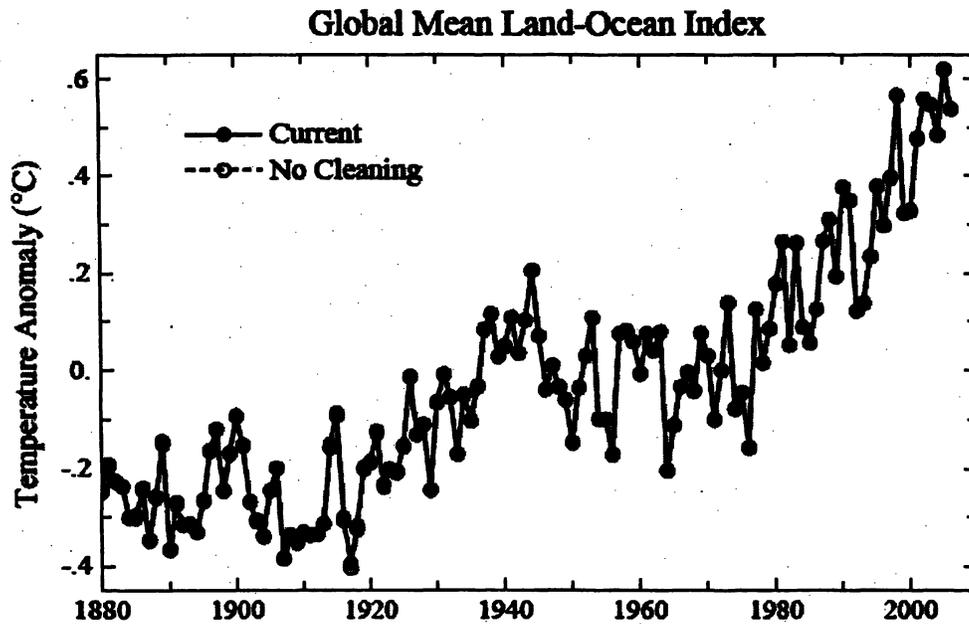

Figure 1 shows maps of the 1880-2006 and 1900-2006 changes of global temperature with and without these stations, and Figure 2 shows the global mean temperature with and without these stations. The effect is practically imperceptible and clearly insignificant.

Another favorite target of those who would raise doubt about the reality of global warming is the lack of quality data from South America and Africa, a legitimate concern. You will note in our maps of temperature change some blotches in South America and Africa, which are probably due to bad data. Our procedure does not throw out data because it looks unrealistic, as that would be subjective. But what is the global significance of these regions of exceptionally poor data? As shown by Figure 1, omission of South America and Africa has only a tiny effect on the global temperature change. Indeed, the difference that omitting these areas makes is to increase the global temperature change by (an entirely insignificant) 0.01C.

This is all the time that I intend to give to this subject, but in case you wonder why we subject ourselves to the shenanigans, there are scientific reasons, repeated here from the "history" introduction to the program description.

GISS Temperature Analysis

History

The basic GISS temperature analysis scheme was defined in the late 1970s by Jim Hansen when a method of estimating global temperature change was needed for comparison with one-dimensional global climate models. Prior temperature analyses, most notably those of Murray Mitchell, covered only 20-90N latitudes. Our rationale was that the number of Southern Hemisphere stations was sufficient for a meaningful estimate of global temperature change, because temperature anomalies and trends are highly correlated over substantial geographical distances. Our first published results (Hansen et al., Climate impact of increasing atmospheric carbon dioxide, *Science* 213, 957, 1981) showed that, contrary to impressions from northern latitudes, global cooling after 1940 was small, and there was net global warming of about 0.4C between the 1880s and 1970s.

Hansen and Lebedeff (Global trends of measured surface air temperature, *J. Geophys. Res.* 92, 13345, 1987) documented the analysis method, showing that the correlation of temperature change was reasonably strong for stations separated by up to 1200 km, especially at middle and high latitudes. They obtained quantitative estimates of the error in annual and 5-year mean temperature change by sampling at station locations a spatially complete data set of a long run of a global climate model, which was shown to have realistic spatial and temporal variability.

This derived error bar only addressed the error due to incomplete spatial coverage of measurements. As there are other potential sources of error, such as urban warming near meteorological stations, etc., many other methods have been used to verify the approximate magnitude of inferred global warming. These methods include inference of surface temperature change from vertical temperature profiles in the ground (bore holes) at many sites around the world, rate of glacier retreat at many locations, and studies by several groups of the effect of urban and other local human influences on the global temperature record. All of these yield consistent estimates of the approximate magnitude of global warming, which has now increased to about twice the magnitude that we reported in 1981. Still further affirmation of the reality of the warming is its spatial distribution, which shows largest values at locations remote from any local human influence, with a global pattern consistent with that expected for response to global

climate forcings (larger in the Northern Hemisphere than the Southern Hemisphere, larger at high latitudes than low latitudes, larger over land than over ocean).

Some improvements in our analysis were made several years ago (*J. Geophys. Res.* 104, 30997, 1999; 106, 23947, 2001) including use of satellite-observed night lights to determine which stations in the United States are located in urban and peri-urban areas, the long-term trends of those stations being adjusted to agree with long-term trends of nearby rural stations.

[As you will see in the latter paper we found 1934 and 1998 to be in a statistical tie for warmest U.S. year, 1934 being warmer by an insignificant couple hundredths of a degree. We still find that result. The minor flaw recently found in our data analysis, which affected U.S. temperatures by 0.15C after 2000, did not alter this result. Pundits picking up on this non-story did not get this right, and further they tried to leave the impression that they were talking about global temperature. Ah me.]

You may wonder why we bother to put up with this hassle and the nasty e-mails that it brings. Well, there are at least a couple of good reasons.

First, there is scientific value in having near-real-time global temperature analysis, it is fairly easy to run the program as new data come in each month, and a lot of people tell us that our analysis and presentations are useful to them. There is merit in having more than one group do the analyses because the results differ somewhat. For example, in 2005 we were the only group initially reporting 2005 as being, on global mean, the warmest year in the record. We would not have obtained that result without our method of extrapolating estimates of anomalies out to distances of 1200 km from the nearest station. Later checks with satellite infrared data indicated that our Arctic and Greenland warm anomalies were, if anything, conservative. And the interactions with the NOAA and British groups have been extremely friendly and fruitful and in the spirit of good science, and good science is fun.

Second, the climate change problem is important.

"Peak Oil" Paper Revised and Temperature Analysis Code

To be removed from Jim Hansen's e-mail distribution respond with
REMOVE in subject line.

(1) The paper "Implications of 'Peak Oil' for Atmospheric CO2 and
Climate", recently revised and resubmitted to Environmental
Research
Letters, is available at XXXXXXXXXXXX.

A principal concern of both referees was our use of a pulse-
response
function, fit to the Bern carbon cycle model, as opposed to a
detailed
carbon cycle model. We have clarified limitations of a
pulse-response function, but frankly we consider the
simplicity and
transparency of this approach to be a merit, not a fault. We are
concerned mainly with scenarios that have a chance of avoiding
"dangerous" CO2 levels, in which case the strong positive
feedbacks
found in some climate-carbon models are less likely, and in any
case
such feedbacks only add to the dichotomy between scenarios with
declining emissions and "business-as-usual" scenarios.

We have minimized reference to a "dangerous" atmospheric CO2
level to
satisfy one of the referees. We retained one reference to our
recent
papers, which are published in peer-reviewed journals and, we
believe,
make a strong case that we are already close to a dangerous CO2
level.

The principal conclusion of this paper is that it is possible to
keep
atmospheric CO2 at a much lower limit than commonly assumed,
provided

that coal use is phased out except where the CO₂ is captured and stored. This paper provides some of the rationale for the discussion in "Old King Coal II".

(2) Temperature Analysis Code

Reto Ruedy has organized into a single document as well as practical on a short time scale the programs that produce our global temperature analysis from publicly available data streams of temperature measurements. These are a combination of subroutines written over the past few decades by Sergej Lebedeff, Jay Glascoe, and Reto. Because the programs include a variety of languages and computer unique functions Reto would have preferred to have a week or two to combine these into a simpler more transparent structure, but because of a recent flood of demands for the programs, they are being made available as is. People interested in science may want to wait a week or two for a simplified version.

An introduction to the program description defines the scientific purposes. We have also made a few graphs that may help clarify the significance (or lack thereof) of criticisms in the blogosphere. The one aspect of our procedure where subjectivity could come into play is the choice of which stations are eliminated from the record. This is based on identifying the (small fraction of) stations that raise a red flag (e.g., deviation of 5 standard deviations are more, or a large temporal discontinuity, as defined in our papers). I compared the records of these stations were compared with records of the nearest stations; if these displayed similar features the records were retained. We provide here the list of stations eliminated.

Figure 1 shows maps of the 1880-2006 and 1900-2006 changes of global temperature with and without these stations, and Figure 2 shows the global mean temperature with and without these stations. The effect is practically imperceptible and clearly insignificant.

<x-flowed>
Jim,

No, it looks 23 of the 26 warmest were since 1980. (19 out of 20 warmest was since 1980.) (<http://data.giss.nasa.gov/gistemp/taledata/GLB.Ts+dSST.txt>)

#1	2005	0.62
#2	1998	0.57
#3	2002	0.56
#4	2003	0.55
#5	2006	0.54
#6	2004	0.49
#7	2001	0.48
#8	1997	0.40
#9	1995	0.38 (0.381)
#10	1990	0.38 (0.378)
#20	1944	0.21
#24	1973	0.14
#26	1977	0.13

Before 1998, 1997 was the record warm year, the difference between these two are 0.168 degC. So it is correct to say 0.2 degC and 0.3 degF.

Dear Jim,

I have a favor to ask. Could you please look over these two sentences from our new Oxford University Press book and say whether they are correct, and if not provide a corrected version?

Twenty-five of the twenty-six warmest years since global temperatures were first accurately recorded in 1856 have occurred since 1980. In 1998, the average global surface temperature set a new record by a wide margin, exceeding that of the previous record year, 1997, by about 0.3 degree °Fahrenheit (0.2 degree °Celsius). This 1998 record was surpassed in 2005.

That would be very much appreciated.

with very best wishes,
eric

Thank you, Reto. I am glad I noticed before some outsider do. See you later.

Makiko

On 9/11/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Makiko,

Thanks for noticing that - since we changed to using the newest USHCN, the output files were moved to a special directory and the culled versions were never created. So, except for the homogenized data, the station data were still the same as a month ago.

I changed the new script and updated all station data.

<x-flowed>

Jim,

No, it looks 23 of the 26 warmest were since 1980. (19 out of 20 warmest was since 1980.) (<http://data.giss.nasa.gov/gistemp/tabledata/GLB.Ts+dSST.txt>)

#1	2005	0.62
#2	1998	0.57
#3	2002	0.56
#4	2003	0.55
#5	2006	0.54
#6	2004	0.49
#7	2001	0.48
#8	1997	0.40
#9	1995	0.38 (0.381)
#10	1990	0.38 (0.378)
#20	1944	0.21
#24	1973	0.14
#26	1977	0.13

Before 1998, 1997 was the record warm year, the difference between these two are 0.168 degC. So it is correct to say 0.2 degC and 0.3 degF.

Dear Jim,

I have a favor to ask. Could you please look over these two sentences from our new Oxford University Press book and say whether they are correct, and if not provide a corrected version?

Twenty-five of the twenty-six warmest years since global temperatures were first accurately recorded in 1856 have occurred since 1980. In 1998, the average global surface temperature set a new record by a wide margin, exceeding that of the previous record year, 1997, by about 0.3 degree °Fahrenheit (0.2 degree °Celsius). This 1998 record was surpassed in 2005.

That would be very much appreciated.

with very best wishes,
eric

Jim,

Steve is still having fun with step0, but eventually he'll find that we did not document how we determined the US brightness numbers we use in our homogeneization.

Checking that step, I noticed that the program that reads Stutzer's file is machine dependent, because some stations lie on the edge between 2 cells. If in these cases I use the brighter of the 2 cells the choices become more robust. 8 of the about 400 rural stations would become peri-urban, and since we don't distinguish between urban and peri-urban stations, these would be the only effective changes.

I looked at the US annual mean series in both cases: they differ by less than .003 C except between 1880 and 1900; in 1900 the difference new-old

is -0.005C, in 1880 +.014C .

I would prefer to use add the newer version into the sources. I'd also like to take the text out of the tar file and make it available separately - this is probably the only thing that any normal person might be interested in. The big brightness file should probably also be stored separately for the convenience of those who would just want to look at the programs.

By the way, Steve's newest "discovery" about the Detroit file is simply due to our switch from USHCN-1999 to USHCN-2005.

He also claims (not in any email, just in his blogs - so it may not be true), USHCN-2006 is also available; I know that NOAA has it but I can't find it on the USHCN site.

Jim, Reto,

Since Reto switched to USHCN data through 2005 this month, I was curious how it changed. (Reto showed me some graphs, but I wanted to see them myself.) Since I didn't get annTs_Map180x90xxx data, I went to athena:/clim1/Steve and took a look at US_ann.lpl.neat. Is this with the new data set, Reto? Now I see 1934 = 1.24 and 1998 = 1.24, tie!

What should I do? Switch to this data on <http://data.giss.nasa.gov/gistemp/graphs/>? Or leave it as last month data (with USHCN through 1999)? Since I wrote on the top of the page, we extended our use of USHCN to 2005, I'd better switch to new one, but then again these crazy people may say, now we have 1934 and 1998 in tie. Which is true? Why did we change? etc, etc.

Reto,

I am glad that Ken Bell could fix your e-mail problem,

I thought about showing both US means; USHCN through 1999 and USHCN through 2005. $T(1934) = 1.25$ and $T(1998) = 1.23$ before and $T(1934) = T(1998) = 1.24$ now. But Jim wonders (and so I do) why using USHCN for 2000-2005 changes the mean temperature before 2000. After we understand why, I will show both data.

Thank you,
Makiko

On 9/12/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Reto,

Yes, now I remeber that you had told me that USHCN data were cleaned more, dropping many stations which Jim had eliminated. I was just forgetting about it when I talked with Jim on the phone just before I left work. I am sorry.

Now my question is that

when you were using USHCN through 1999 and switching to GHCN from 2000, you matched the GHCN and USHCN means for 1990-1999, right?

now when you use USHCN through 2005 and use GHCN for 2006 and 2007, do you match the GHCN and USHCN means for 1996-2005?

It is getting late, so I hope you go home soon and I will ask you tomorrow.

Good night,
Makiko

Jim,

How do you want to do it? On the GISS temperature web page, below six figures and above "background", do you want to have "What's New" and write "The use of the USHCN statio data was extended to 2005 from 1999" and the US mean and global mean small graphs on the same page, which can be clicked to get enlarged? I will make the graphs today but won't put them on the web page until we talk about it more on the phone today or face-to-face tomorrow. I think you'd better concentrate on the Hawaii paper today, so probably we should do it tomorrow.

<x-flowed>

Jim,

I have US and global means for

(a) USHCN through 1999, with all data through July 2007
and

(b) USHCN through 2005, with all data through August 2007.

Can I compare these two cases? Or should I ask Reto to create

(c) USHCN through 1999 and with all data through August 2007,
if he hasn't made this yet?

Comparison of (b) and (c) is totally the USHCN period change, and the difference between (a) and (c) are due to additions of some station data and NOAA modifications which may affect very little to the annual means through 2006.

<x-flowed>
Jim,

I made comparisons of the old data and the new data and put them at the top of [http://www.giss.nasa.gov/~makis/GISS Temp/](http://www.giss.nasa.gov/~makis/GISS_Temp/) where others can't see.

Reto made a good point. He says I should not use the words "USHCN through 1999" and "USHCN through 2005" but "USHCN 2000 version" and "USHCN current version". He is right because the newer version not just go through 2005 but also they cleaned data for 1880-1999. But do you think it is clear if I write "2000 version" and "current version"? Maybe I should add a sentence describing "2000 version" is through 1999 and the current version is through 2005? How do you want it?

I can wait to put this on the web (for the public) tomorrow.

Makiko

Jim,

I have US and global means for
(a) USHCN through 1999, with all data through July 2007
and
(b) USHCN through 2005, with all data through August 2007.
Can I compare these two cases? Or should I ask Reto to create
(c) USHCN through 1999 and with all data through August 2007,
if he hasn't made this yet?

Comparison of (b) and (c) is totally the USHCN period change, and the difference between (a) and (c) are due to additions of some station data and NOAA modifications which may affect very little to the annual means through 2006.

I believe that the statement that the USHCN data were updated with the 2005 data available from such-and-such website should be accompanied by line graphs of the U.S. and global temperature showing the results before and after. Jim

On 9/12/07, Makiko Sato <<mailto:makis@giss.nasa.gov>makis@giss.nasa.gov > wrote:

Reto,

Yes, now I remeber that you had told me that USHCN data were cleaned more, dropping many stations which Jim had eliminated. I was just forgetting about it when I talked with Jim on the phone just before I left work. I am sorry.

Now my question is that

when you were using USHCN through 1999 and switching to GHCN from 2000, you matched the GHCN and USHCN means for 1990-1999, right?

now when you use USHCN through 2005 and use GHCN for 2006 and 2007, do you match the GHCN and USHCN means for 1996-2005?

It is getting late, so I hope you go home soon and I will ask you tomorrow.

Good night,

Makiko

I thought "USHCN 2000 Version (data through 1999)
USHCN Current Version (data through 2005)" may not be enough, so I added some
sentences in the tables

Global Temperature Anomaly (C)
(Land-Ocean Index)

Year	USHCN Versions		Note: Current version not only has data extended to 2005 but also data for 1880-1999 have been cleaned by NOAA.
	2000 (data through 1999)	Current (2005)	
1880	-.25	-.25	
1881	-.20	-.20	

on [http://www.giss.nasa.gov/~makis/GISS Temp/GLB USHCN.2005vs1999.txt](http://www.giss.nasa.gov/~makis/GISS_Temp/GLB_USHCN.2005vs1999.txt)

and

U.S. Temperature Anomaly (C)

Year	USHCN Versions		Note: Current version not only has data extended to 2005 but also data for 1880-1999 have been cleaned by NOAA.
	2000 (data through 1999)	Current (2005)	
1880	-.26	-.24	
1881	.29	.29	

on [http://www.giss.nasa.gov/~makis/GISS Temp/US USHCN.2005vs1999.txt](http://www.giss.nasa.gov/~makis/GISS_Temp/US_USHCN.2005vs1999.txt).

Do you think it is not necessary, or do you have better words?

Subject: "graphs" page

From: "Makiko Sato" <makis@giss.nasa.gov>

Date: Sat, 15 Sep 2007 05:35:47 -0400

To: "Reto Ruedy" <rueedy@giss.nasa.gov>, "Robert B. Schmunk" <rschmunk@giss.nasa.gov>

Reto, Robert,

Jim and I worked yesterday evening on "What's New" on the graphs page.

If there are some corrections/suggestions, please let me know. It is pointing to a "Updates to Analysis" section on temperature home page which doesn't exist until Jim gets back next Wed. or Thurs. , but he said it is OK.

On 9/15/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Jim, Makiko,

Since the changes mainly affect this page and the station data page, this is the proper place to put this section. We might want to add a link to it on the station data page.

Yes, we were going to keep these in here.

On the station data page, we might also want to include the caveat, that only the raw GHCN data are suitable for local studies; the other stages are only useful to compute regional anomalies and trends for regions larger than 300,000 square miles.

It might be good to add in the "what's new" section to a) the corresponding graph as in c).

We thought about it, but the difference in (a) and (c) are, for (c) there is no write-ups, and for (a) if you click, you can see graphs right away, so we just mentioned they show graphs and maps.

The section after "what's new" might profit from being titled "How does 2007 compare to the 2 hottest years?"

Yes, it is a good idea, so I will add it Monday.

Thank you,
Makiko

Jim,

I was talking about

*** What's New ***

(c) Sept. 10, 2007: We switched to the current version of USHCN data set which includes data through 2005. The effect of this change is shown by the following graphs and tables. (See "Updates to Analysis" section on GISS Temperature page for more details.)

large GIF, PDF

Tables of Comparisons Global, US

(b) Sept. 7, 2007: GISS temperature analysis computer programs and data sets were made available. See "'Peak Oil" Paper Revised and Temperature Analysis Code" for discussions including graphs and maps showing effects of data cleaning.

(a) Aug. 7, 2007: Changes were made to correct a discontinuity in records of U.S. stations included in both USHCN and GHCN. See "A Light On Upstairs?" (Aug. 10) and "The Real Deal: Usufruct & the Gorilla" (Aug. 16), which include graphs and maps, for discussions of the impact of the changes.

On 9/15/07, James Hansen <jhansen@giss.nasa.gov> wrote:

Not quite sure what locations are being referred to, but we need to have all key info on the first page of GISTEMP. What I am hoping is that Rob can make a clever way of having everything important there in a small enough space, e.g., by starting out with the first few lines of paragraph of a section that is completed in an attachment. Thus the main page will direct users to the important results, with an indication of what they include.

I can see why the public has been confused as we presently offer practically no identifiable explanation of recent changes.

I think that it is important to put this stuff up soon. It does not need to be the final format and the list of changes does not have to be complete. But try to avoid putting up something that is later embarrassing.

On 9/15/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Jim, Makiko,

Since the changes mainly affect this page and the station data page, this is the proper place to put this section. We might want to add a link to it on the station data page.

Yes, we were going to keep these in here.

On the station data page, we might also want to include the caveat, that only the raw GHCN data are suitable for local studies; the other stages are only useful to compute regional anomalies and trends for regions larger than 300,000 square miles.

It might be good to add in the "what's new" section to a) the corresponding graph as in c).

We thought about it, but the difference in (a) and (c) are, for (c) there is no write-ups, and for (a) if you click, you can see graphs right away, so we just mentioned they show graphs and maps.

The section after "what's new" might profit from being titled "How does 2007 compare to the 2 hottest years?"

Yes, it is a good idea, so I will add it Monday.

Thank you,
Makiko

Reto

Reto, Robert,

Jim and I worked yesterday evening on "What's New" on the graphs page.

If there are some corrections/suggestions, please let me know. It is pointing to a "Updates to Analysis" section on temperature home page which doesn't exist until Jim gets back next Wed. or Thurs. , but he said it is OK.

Jim,

In the description of step2 (homogeneization) "urban" should be replaced by "urban and peri-urban" or "non-rural" or we may add a sentence to indicate that "small-town" stations are adjusted the same way as urban stations. Although it is mentioned at the end of the previous section, it should probably be repeated here to avoid accusations of inconsistency.

let's use: "urban and peri-urban (i.e., other than rural)" that makes an unambiguous definition of our categories

April 2006 modification:

Looking at maps based on ocean data alone, we noticed that the HadISST data (1880-1981) extended to regions containing sea ice, whereas the NOAA data (1982-present) did not. In order to get a more consistent time series, the HadISST part was restricted to the same ice-free regions as the NOAA data. Since the temperature of water containing ice is always near the freezing point, including data from such regions tends to artificially dampen any heating or cooling trend.

April 2006 modification: HadISST ocean temperatures are now used only for regions that are identified as ice-free in both the NOAA and HadISST records. This change effects a small number of gridboxes in which HadISST has sea ice while NOAA has open water. The prior approach damped temperature change at these gridboxes because of specification of a fixed temperature in sea ice regions. The new approach still yields a conservative estimate of surface air temperature change, as surface air temperature usually changes markedly when sea ice is replaced by open water or vice versa. Because of the small area of these gridboxes the effect on global temperature change was negligible.

A preliminary re-working of the GISTEMP homepage is at

http://data.giss.nasa.gov/gistemp/index_new.html

Although very long, it could go up as-is in place of the current GISTEMP homepage except that the links to the Columbia webpage stuff are not there yet (i.e., in the second para of the Aug 2007 update comments).

I am very concerned about linking directly to the PDFs on the Columbia webpage, whether here or on the graphs page as Makiko has already done, because it is transparent to the user that the PDFs are located on Jim's personal webpage. All they know is that they click on a link on a NASA webpage and they get a PDF. Hence the inattentive user (which would be most of them) would think the PDF is a NASA document.

So on Sunday I will try to make a pass through the PDFs and extract out the material which can be posted on a NASA webpage. I would assume this would mostly mean toning down or eliminating language re: skeptics and denialists.

Also, Makiko, I cleaned up the HTML of the "what's new" you put at the start of the graphs webpage.

Thank you for cleaning.

Is the "(a)", "(b)",

"(c)" notation necessary? I left it there, but can't see that it needs to be there.

It's only my habit to number (order) things. I thought if I put in order of (c), (b), (9), people will know the bottom one came first because they may not look at dates I put. But you are right, I think Americans don't like graphs or numbers much, so please remove them.

On 9/17/07, James Hansen <jhansen@giss.nasa.gov> wrote:

You make some good points. I think of my response as a blunt statement of the truth, but others can view it as editorializing. It is 3 AM so I just note that we did thank Mc He has tried to mislead in several ways. We only make changes that make scientific sense, and we should not stop doing that. We have now listed those on the first page of the temperature web page.

Regarding the question of editorializing...I did a lot of soul searching before noting in a talk two years ago that the global warming story was being distorted by special interests ..my Keeling talk at AGU ...most people now believe that this was a good thing to do...if we just report the science and do not make note of misinformation, it is not clear that the message gets out, and we are running out of time.

Jim Hansen

On 9/18/07, @sbsoft.com> wrote:

Dear Sir:

I don't understand your recent approach in dealing with the recent criticisms of Steve McIntyre and friends.

As you recently noted (and McIntyre agrees), none of these criticisms have a material effect on global temperature.

The credibility of GISS (and other organizations aggregating temperature data) DOES have a material impact on any analysis of global temperature.

If McIntyre shows that you have an agenda, then your data (and the conclusions supported by your data) are weakened.

By making undocumented changes to your methodology (which McIntyre subsequently dissects on his blog) you provide ammunition to those who insist that you have agenda, and that your agenda is tainting your data.

Why not adopt an ultraconservative approach in all of the changes that you make? Why not:

1. avoid making changes except in the case of outright errors
2. publicly document all changes at the time they occur
3. graciously thank McIntyre et al for any errors they bring to your attention
4. avoid making editorial statements, and let the data speak for itself.

It makes no difference whether 1934 or 1998 was warmer in the United States.

But your recent statements and changes have created the impression that GISS

cares about this issue, and is willing to change its methodology accordingly.

It makes little difference whether or not this is true. What matters is whether or not you have created a trail of data that would allow an observer

to reach the conclusion that your agenda has impacted your actions.

I think you have, and that this is infinitely more damaging than a temperature adjustment here or there.

Sincerely,

What data comparison? The comparison due to the newest change, i.e. USHCN from 2000 to current version, is still there. I wrote "Tables: Global, US" in a separate line below the graphs, but now Robert changed to "Also see tables of comparisons for http://data.giss.nasa.gov/qistemp/graphs/GLB_USHCN.2005vs1999.txt>globe and http://data.giss.nasa.gov/qistemp/graphs/US_USHCN.2005vs1999.txt>US-only." as an additional sentence, so you may have not noticed it.

Otherwise, I don't remember the data comparison. I can make such things for USHCN/GHCN problem fixing.

Jim,

At the Economic Policy Institute last Friday we had a good discussion on greenhouse gas taxes and other means of making the shift and my message to them that we can impose tariffs now on the GHG's associated with imports as long as they accurately reflect our domestic producers' costs of controlling pollution or paying for it, was well received. I also suggested using the proceeds for loans back to the tariffed countries to help them cut GHG in the production methods. Eventually we would need to embargo goods from recalcitrant countries just as the world has banned trade in highly endangered species and whales, and ozone depleting chemicals, etc. SCB submitted testimony on that to House Ways and Means.

You should add that to your speech I think since both sides will wait for the other to act unless we force the issue.

Dear Dr Ruedy,

Thank you for this information and for the courteous acknowledgement at your website. I can now see where your post-2000 data comes from, but I remain unable to identify a digital source for your data prior to 2000 from available information. I have compared GISS raw to all the archived USHCN versions and have been unable to find a match for US data. In some cases, the differences are substantial.

Can you provide me with (1) a URL from which the U.S. data prior to 2000 (in the version that you used) can be downloaded. (2) If this is no longer possible due to the passage of time, could you please provide me with a copy of the data that you used (or upload it to an area of your FTP site) and also provide its provenance and date of acquisition? Obviously mere print citations are inadequate for this purpose.

I would like to assess the impact of these modifications on the US and global averages for myself. I would appreciate a copy of the source code used for these calculations.

Regards, Steve McIntyre

Subject: Re: GISS Raw Data

Dear Sir,

As to the question about documentation, the basic "GISS Surface Temperature Analysis" page starts with a "Background" section whose first paragraph contains the sentence: "Input data for the analysis ,..., is the unadjusted data of GHCN, except that the USHCN station records were replaced by a later corrected version". A similar statement appears in the "Abstract" and the "Introduction" section of our 2001 paper (JGR Vol 106, pg 23,947-23,948). The Introduction explains the above statement in more detail.

In 2000, USHCN provided us with a file with corrections not contained in the GHCN data. Unlike the GHCN data, that product is not kept current on a regular basis. Hence we used (as you noticed) the GHCN data to extend those data in our further updates (2000-present).

I agree with you that this simple procedure creates an artificial step if some new corrections were applied to the newest data, rather than bringing the older data in sync with the latest measurements - as I naively assumed. Comparing the 1999 data in both data sets showed that in about half the cases where the 1999 data were changed, the GHCN data were higher than the USHCN data and in the other half it was the other way round with the plus-corrections slightly outweighing the minus-corrections.

Although trying to eliminate those steps should have little impact on the US temperature trend (much less the global trend), it seems a good idea to do so and I'd like to thank you for bringing this oversight to our attention.

When we did our monthly update this morning, an offset based on the last 10 years of overlap in the two data sets was applied and our on-line documentation was changed correspondingly with an acknowledgment of your contribution. This change and its effect will be noted in our next paper on temperature analysis and in our end-of-year temperature summary.

The effect on global means and all our tables was less than 0.01 C. In the display most sensitive to that change - the US-graph of annual means - the anomalies decreased by about 0.15 C in the years 2000-2006.

Respectfully,

Reto A Ruedy

To: "Andrew Revkin" <anrevk@nytimes.com>
CC: gschmidt@giss.nasa.gov, "Reto Ruedy" <cdrar@giss.nasa.gov>

Hi Andy,

This seems to be a tempest inside somebody's teapot dome. One of the changes that we made in our analysis in 2001 was to include improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations ARE in the GHCN record, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in the records at those stations, some up, some down.

The net effect averaged over the U.S. was an error of about 0.15C or less in the post-2000 years, well within the uncertainty bar that we give. The effect on the global mean was of the order of a thousandths of a degree, i.e., entirely negligible.

It is unclear why anyone would try to make something out of this, perhaps a light not on upstairs? Or perhaps this is coming from one of the old contrarians? They can't seem to get over the fact that the real world has proven them to be full of malarkey! You would think that they would be ready to crawl under a rock by now!

Jim

(Reto, please correct if there is anything in the above that is not right.)

Reto,

I am being besieged by e-mails and calls about this, so we need to do something promptly, as there will be stories written today for publication tomorrow. Let me know what the chances are that you will be able to have the comparative global temperature curves that we discussed yesterday.

By the way, Makiko, do you remember if we ever make any statement about how different years ranked for the United States temperatures? There are several demands that we issue a press release correcting our wrong results and declaring that 1934 is now the warmest year on record in the U.S., also that 4 of the 10 warmest years were in the 1930s and only 3 in the last 10 years.

To: "Makiko Sato" <makis@giss.nasa.gov>, "Reto Ruedy" <cdrar@giss.nasa.gov>

Makiko, Reto,

I am being beseiged by these (see below). The appropriate response is to show the curves for U.S. and global temperatures before and after (before and after McIntyre's correction). Makiko doubts that this is possible because the earlier result has been "thrown away". We will never live this down if we give such a statement. It must be possible to reconstruct the "before" result. Unfortunately, this needs to be done soon, as there are various writers with deadlines this afternoon. I hope that is possible -- this should have a higher priority than the calculation that we mentioned yesterday.

Jim

By the way, I think that we should save the results of the analyses at least once per year, so we will have a record of how they change.

Subject: GISS - Truth driven vs agenda driven

Dear Leslie,

My fellow Canadians have unveiled another Global warming scam - yours!

Now that we know Mr. Hansen used incorrect data or procedures in determining the "hottest years", concluding that the top 5 warmest years since the 1890s are : 2005, 1998, 2002, 2003, 2006.

Yet, there on your website (<http://www.giss.nasa.gov/research/news/20070208/>) is the information still making what is now known to be a bogus claim.

Yes we are at a tipping point all right. And the truth is spilling all over your pro-AGW agenda.

Just like Mr. Manns infamous Hockey Stick graph, which was proven fraudulent by the same people who found your glaring errors, another lie bites the dust. Funny thing is, when they determined Mr. Mann was fudging things, they found that Mr. Mann's "peer reviewed" work was reviewed but not put through a rigorous, truth seeking, audit. That led to them forming climateaudit.org, to apply the audits that are so obviously missing from the process. And BINGO - Mr. Hansen is unmasked as a zealot.

Now, are you honestly a scientific driven institution, or will you admit to being an agenda driven one? I await the press conference to announce that you have had to revise the hottest years list. I await the update to your website to reflect the new, peer-audited, results. I await the confession that you made a huge mistake. I await the firing of those who created and flogged this lie.

Will you do the right thing?

Sincerely

Hi Reto,

Thanks for the heads up on this and glad we don't have to change anything because it's printed and done. Looks very nice and I'll be sending complimentary copies your way once it is published. We'll keep your email in the file in case we receive letters about this.

Best,
Kris

Subject

Y2K correction

Hi Kris,

Steve McIntyre, a former mining executive, now a blogger and global warming denier, is blowing a small correction in our procedure of handling US data way out of proportion. The correction has absolutely no impact on the global mean temperature time series, over the US it made a difference of .15 C.

I checked what this correction does to your map and it does change the colors somewhat over parts of the US; the rest of the world is unaffected. Even the change over the US is way within the margin of error (0.5 C). So there is little need to make any changes.

The timing is a bit awkward, though. Sorry for that,

Reto

Subject: Years of bad data corrected; 1998 no longer the warmest year on record

To: James.E.Hansen@nasa.gov

Dear Dr. Hansen,

I'm doing some research on anthropological global warming. The problem I'm having now is that NASA has now released corrected figures, and the changes are truly astounding. The warmest year on record is now 1934. 1998 (long referred to as record-breaking) moves to second place. 1921 takes third. In fact, 5 of the 10 warmest years on record now **all occur before World War II**. This change leads me to believe NASA is being manipulated by those who "deny" the globe is in a warming trend. Could you please help me understand these revelations? Thank you and have a nice day.

Sincerely,

A Light On Upstairs?

To be removed from Jim Hansen's e-mail list respond to sender with REMOVE as subject

Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. and a thousandth of a degree over the world.

Recently it was realized that the monthly more-or-less-automatic updates of our global temperature analysis (XXXXXX –link to 2001 paper) had a flaw in the U.S. data. In our most recent update of the analysis method (originally published in our 1981 Science paper – LINK HERE) we included improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations ARE in the GHCN (Global Historical Climatology Network) data stream, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in the records at those stations, some up, some down. This problem is easy to fix, by matching the 1990s decadal-mean temperatures for the NOAA-corrected and GHCN records, and we have made that correction.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15C, as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousands of a degree, so the corrected and uncorrected curves are indistinguishable.

Somehow this data flaw was advertised on the internet and for two days I have been besieged by rants that I have wronged the President, that I must "step down", or that I must "vanish". Hmm, I am not very good at magic tricks.

I am always a bit puzzled by the views that seem to come from conservative extremes, a bit disconcerting as I come from a moderately conservative state and consider myself a moderate conservative in most ways – puzzling because it seems to me that conservatives should be the first ones standing up for preserving Creation and for the rights of the young and the unborn. After all, that is the basic intergenerational issue in global arming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem.

Jim

LightUpstairs.10Aug2007.doc	Content-Type: application/msword Content-Encoding: base64
-----------------------------	--

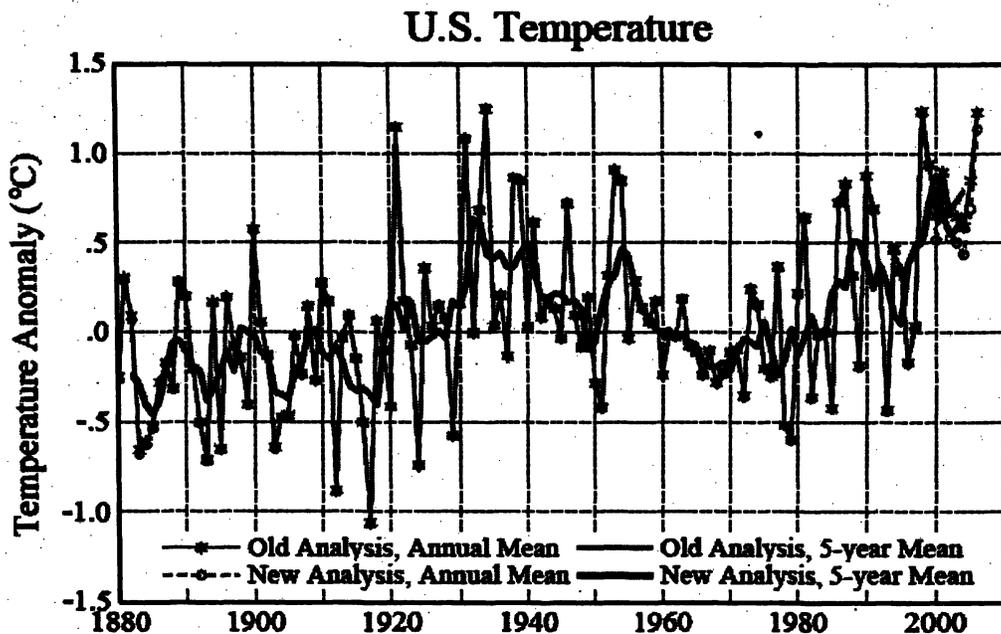

A Light On Upstairs?

Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. and a thousandth of a degree over the world.

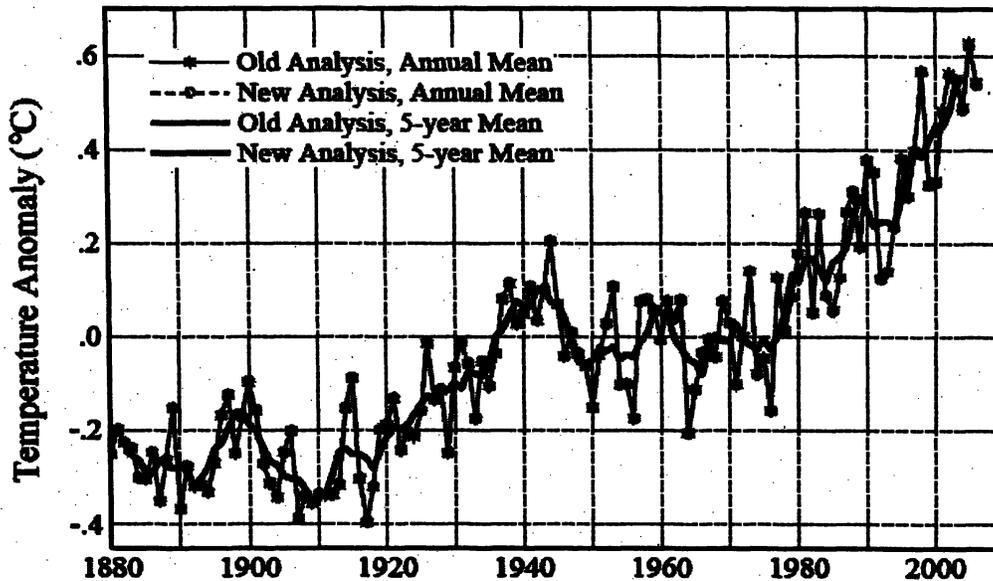

Recently it was realized that the monthly more-or-less-automatic updates of our global temperature analysis (http://pubs.giss.nasa.gov/docs/2001/2001_Hansen_etal.pdf) had a flaw in the U.S. data. In that (2001) update of the analysis method (originally published in our 1981 Science paper – http://pubs.giss.nasa.gov/docs/1981/1981_Hansen_etal.pdf) we included improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations are in the GHCN (Global Historical Climatology Network) data stream, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in 2001 in the records at those stations, some up, some down (over U.S. only). This problem is easy to fix, by matching the 1990s decadal-mean temperatures for the NOAA-corrected and GHCN records, and we have made that correction.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15C, as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousandths of a degree, so the corrected and uncorrected curves are indistinguishable.

Global Temperature (Land-Ocean Index)

Contrary to some of the statements flying around the internet, there is no effect on the rankings of global temperature. Also our prior analysis had 1934 as the warmest year in the U.S. (see the 2001 paper above), and it continues to be the warmest year, both before and after the correction to post 2000 temperatures. However, as we note in that paper, the 1934 and 1998 temperature are practically the same, the difference being much smaller than the uncertainty.

Somehow the flaw in 2001-2007 U.S. data was advertised on the internet and for two days I have been besieged by rants that I have wronged the President, that I must "step down", or that I must "vanish". Hmm, I am not very good at magic tricks.

My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem, though.

A Light On Upstairs?

Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. and a thousandth of a degree over the world.

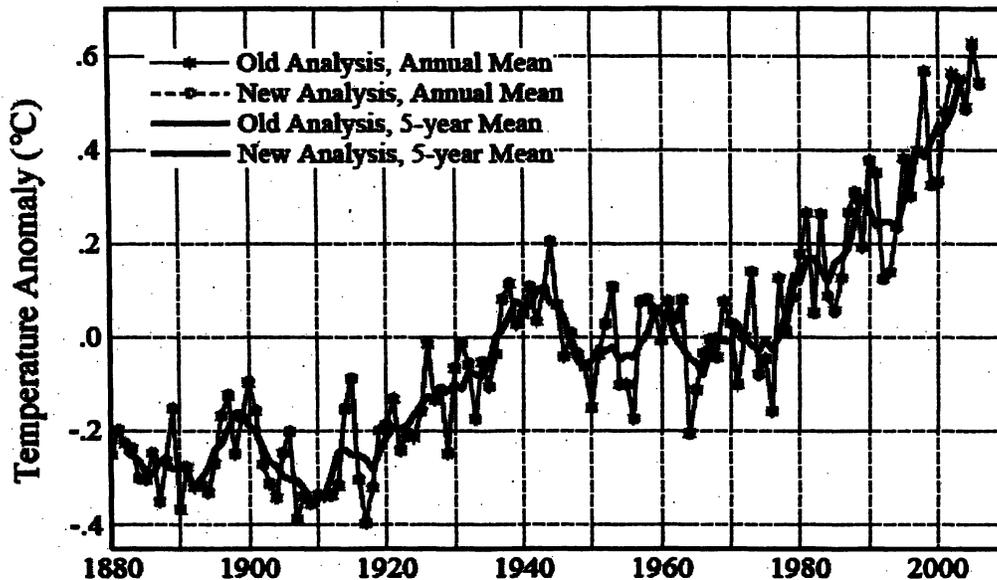

Recently it was realized that the monthly more-or-less-automatic updates of our global temperature analysis (http://pubs.giss.nasa.gov/abstracts/2001/Hansen_etal.html) had a flaw in the U.S. data. In that (2001) update of the analysis method (originally published in our 1981 Science paper – http://pubs.giss.nasa.gov/abstracts/1981/Hansen_etal.html) we included improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations are in the GHCN (Global Historical Climatology Network) data stream, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in 2001 in the records at those stations, some up, some down (over U.S. only). This problem is easy to fix, by matching the 1990s decadal-mean temperatures for the NOAA-corrected and GHCN records, and we have made that correction.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15°C , as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousandth of a degree, so the corrected and uncorrected curves are indistinguishable.

Global Temperature (Land-Ocean Index)

Contrary to some of the statements flying around the internet, there is no effect on the rankings of global temperature. Also our prior analysis had 1934 as the warmest year in the U.S. (see the 2001 paper above), and it continues to be the warmest year, both before and after the correction to post 2000 temperatures. However, as we note in that paper, the 1934 and 1998 temperature are practically the same, the difference being much smaller than the uncertainty.

Somehow the flaw in 2001-2007 U.S. data was advertised on the internet and for two days I have been besieged by rants that I have wronged the President, that I must "step down", or that I must "vanish". Hmm, I am not very good at magic tricks.

My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem, though.

Jim

Your e-mail should be framed, as a counterweight to the all the viscous ad hominem e-mails that have descended through the ethernet.

The answer to your first question is in the attachment. You will see that the flaw in the analysis was of a sort that might occasionally happen, without being detected for a while because the effect is so small. (The large effect claimed in some of the hate-mails was apparently due to some people confusing conclusions about which year was warmest in the United States and which year was warmest on the global average.)

The answer to your second question is that this matter has no effect whatever on climate models or the interpretation of results from climate models, as you can infer yourself once you have looked at the response to your first question.

Jim Hansen

Dr. Hansen,

I am a student at Fairmont State University. Today FOX news reported that a change in temperature modeling by GISS seriously undermines global warming claims. Rather than duke it out in the streets with people who watch FOX religiously, I decided my best course of action was to contact you directly.

Could you please answer two questions for me. First, in layman-dummy talk, what were the recent changes, and second, what does it mean for global climate modeling, especially global warming modeling?

Thank you in advance for your kind patience and reasoned response.

sorry, just noticed this, my box being overfull. The warming (during the industrial era, since the 1800s) in the U.S. is similar to the global warming. Of course, as the contiguous U.S. is only 2% of the global area, the unforced variability is much greater.

Not sure what you mean though -- the "reanalysis" has not changed anything, as you can see by looking at the two graphs that I sent out. The past decade, 1998-2007, is extremely warm in the U.S., about 1.2F warmer than 1951-1980 climatology. The "reanalysis" did not change the fact that we found 1934 to be a hair warmer than 1998 and 2006, but the differences are smaller than the uncertainty. (NOAA NCDC finds 1934 a hair cooler, also insignificant difference.)

As for the future in the U.S., you can look for the warming to become more obvious during the next decade or two, as the competition between GHGs and aerosols shifts more heavily to GHGs.

Jim

On 8/10/07, Andrew Revkin <anrevk@nytimes.com> wrote:

hey jim,

given that quite a few folks (gore and some enviros particularly) have often used the USA temp trends in arguments for action (string of record years) it's hard for me to ignore the reanalysis of those annual temps -- even though my own focus remains global mean temp.

essentially, should people always have paid less attention to US (48 state) trend as a meaningful signal of AGW?

(now that all those earlier warm years intrude, it certainly makes the case that regional data can be a red herring)

happy to discuss briefly by phone.

til 6 p.m. or so

At 11:34 PM 8/9/2007, you wrote:

Hi Andy,

This seems to be a tempest inside somebody's teapot dome. One of the changes that we made in our analysis in 2001 was to include improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations ARE in the GHCN record, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in the records at those stations, some up, some down.

The net effect averaged over the U.S. was an error of about 0.15C or less in the post-2000 years, well within the uncertainty bar that we give. The effect on the global mean was of the order of a thousandths of a degree, i.e., entirely negligible.

It is unclear why anyone would try to make something out of this, perhaps a light not on upstairs? Or perhaps this is coming from one of the old contrarians? They can't seem to get over the fact that the real world has proven them to be full of malarkey! You would think that they would be ready to crawl under a rock by now!

Jim

(Reto, please correct if there is anything in the above that is not right.)

On 8/9/07, Andrew Revkin <anrevk@nytimes.com>

> wrote:

hi,

you probably noticed the mcintyre et al depiction of GISS annual temp estimates for US over time.

were the revisions published yet, or are they updated in databases alone?

also, are you doing same for global mean temp or is this specific issue related to US?

Subject: Temperature change analysis
From: "James Hansen" <jhansen@giss.nasa.gov>
Date: Mon, 13 Aug 2007 23:34:39 -0400
To: "Reto Ruedy" <cdrar@giss.nasa.gov>
CC: "Makiko Sato" <makis@giss.nasa.gov>

Hi Reto,

Sorry that I didn't communicate clearly what I wanted to see in the new run of the analysis program. Two things need to be different from what Makiko showed me.

I know that the USHCN/GHCN business must be frustrating!, but...

First we cannot drop the NCDC improvements to the USHCN. There is no way that we can compete with the person-years of effort that they (Tom Karl and all the others at NCDC) put into that, and they are the experts. Also we have published it and we should continue to follow what we have in that (2001) paper. The correction that you made to stations post 2000 records (by setting the means for 1990 to be equal in the two records?) should be fine, and since we have made that available, we should use that. We don't want still another result, which would really set the pundits happy.

Second, what I want to see is how our new result compares with what we get if we make none of the changes in the table of changes, i.e., do not pick and choose any corrections (such as St. Helena) as being "obviously correct".

CC: "Leslie McCarthy" <lnolan@giss.nasa.gov>

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected by adding the NOAA/NCDC adjustment near the end of the record to the 2001-2007 data, and it has been so corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the *Washington Times* (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the *Spectator*, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even American: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Jim

On 8/14/07, DEMIAN MCLEAN, BLOOMBERG/ NEWSROOM: <dmclean8@bloomberg.net> wrote:

james, pardon me: i see the records volz was referring to are *global*. the u.s. figures showed 1998 as the warmest year. nevertheless, nasa has indeed newly ranked 1934 as the warmest year. also, i'd be grateful if you could respond to the second question, regarding your algorithm and making it public.

best,
demian

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the *Washington Times* (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even American: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb

8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

To: "DEMIAN MCLEAN, BLOOMBERG/ NEWSROOM:" <dmclean8@bloomberg.net>, "Makiko Sato" <makis@giss.nasa.gov>, "Reto Ruedy" <rriedy@giss.nasa.gov>

Makiko, Reto, could you please clear this up. Other people keep saying the same thing that Demian does, i.e., that we previously claimed that 1998 was warmer than 1934. Is that right? I am quite sure that our 2001 paper shows 1934 slightly warmer, as we still find. Of course, scientifically this is all nonsense, as the difference of 0.02 is much less than the accuracy, so practically it should be stated as a tie. I know that whenever new stations are added to the record it can change things by small amounts. Did we once find 1998 as warmer??? Jim (I will be away from e-mail for a few hours).

On 8/14/07, DEMIAN MCLEAN, BLOOMBERG/ NEWSROOM: <dmclean8@bloomberg.net> wrote:

Thanks, James. I'm not familiar with that paper from 2001. Is it not true, though, that NASA's rankings, as available at:

<http://data.giss.nasa.gov/gistemp/graphs/Fig.D.txt>

now show 1934 as the hottest year, where 1998 used to hold that position?

thanks,
demian

At: 8/14 13:00:38

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Jim

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Jim

On 8/14/07, DEMIAN MCLEAN, BLOOMBERG/ NEWSROOM: <dmclean8@bloomberg.net> wrote:

james, pardon me: i see the records volz was referring to are *global*. the u.s. figures showed 1998 as the warmest year. nevertheless, nasa has indeed newly ranked 1934 as the warmest year. also, i'd be grateful if you could respond to the second question, regarding your algorithm and making it public.

best,
demian

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Demian, I am running to a meeting and may not get back in time for your deadline -- following may help answer your question -- presumably you saw my "Upstairs" note? Jim Hansen

----- Forwarded message -----

From: James Hansen <jhansen@giss.nasa.gov>

Date: Aug 14, 2007 2:52 AM

Subject: Re: FW: <no subject>

To: Donald Anderson <donald.anderson-1@nasa.gov>, Jack Kaye <jack.a.kaye@nasa.gov>

Cc: Leslie McCarthy <lnolan@giss.nasa.gov>

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes in NASA's Temperature Data. In an op-ed for the *Washington Times* (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the *Spectator*, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even American: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website

Makiko, Reto, could you please clear this up. Other people keep saying the same thing that Demian does, i.e., that we previously claimed that 1998 was warmer than 1934. Is that right? I am quite sure that our 2001 paper shows 1934 slightly warmer, as we still find. Of course, scientifically this is all nonsense, as the difference of 0.02 is much less than the accuracy, so practically it should be stated as a tie. I know that whenever new stations are added to the record it can change things by small amounts. Did we once find 1998 as warmer??? Jim (I will be away from e-mail for a few hours).

On 8/14/07, DEMIAN MCLEAN, BLOOMBERG/ NEWSROOM: <dmclean8@bloomberg.net> wrote:

Thanks, James. I'm not familiar with that paper from 2001. Is it not true, though, that NASA's rankings, as available at:

<http://data.giss.nasa.gov/gistemp/graphs/Fig.D.txt>

now show 1934 as the hottest year, where 1998 used to hold that position?

thanks,
demian

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Jim

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Jim

On 8/14/07, DEMIAN MCLEAN, BLOOMBERG/ NEWSROOM: <dmclean8@bloomberg.net> wrote:

james, pardon me: i see the records volz was referring to are *global*. the u.s. figures showed 1998 as the warmest year. nevertheless, nasa has indeed newly ranked 1934 as the warmest year. also, i'd be grateful if you could respond to the second question, regarding your algorithm and making it public.

best,
demian

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include

the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the *Washington Times* (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National

Aeronautics and Space Administration? Well, he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Hi Jim,

I heard that GISS revised the US average temperatures based on the email below:

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the Washington Times \leq <http://www.washingtontimes.com/article/20070813/COMMENTARY08/108130024/1012/commentary> \geq (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the 'U.S. surface air temperature' rankings for the Lower 48 states, you might notice something has changed. Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures. The 'hottest year on record' is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century - 2000, 2002, 2003, 2004 - plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived."

I have attached a short write-up related to NOAA's revised stats for contiguous US temperatures. We would be curious to know what the basis is for your revisions.

Cheers, Tom

National temperature trends: The science behind the calculations

On January 9, 2007 NOAA provided a press release stating that preliminary temperatures for the United States indicated 2006 was warmest year on record. Included in the press release was reference to a new method for correcting biases in observations (Version 2) that had a preliminary rank for 2006 as the 2nd warmest on record. After receipt of additional observations for 2006 temperature statistics were updated on May 1, 2007. The late data changed the rank for 2006 to the 3rd warmest on record for the old method (Version 1) and the rank remained as 2nd warmest for the new data correction method (Version 2).

Why such changes occur is rooted both in the way the observations are processed for quality and the delay in receipt of data on paper records from many stations. The observations come from the U.S. Historical Climatology Network (USHCN), a network of 1221 climate observing stations in the continental United States (<http://www.ncdc.noaa.gov/oa/climate/research/ushcn/>). These data are extensively quality controlled for errors and for small biases that may have occurred through time due to artificial changes at each observing station. These artificial changes include station relocations, different instrumentation, and changes in the landscape surrounding the station (e.g. urbanization, removal or planting of vegetation, etc.). Some of these changes may result in "random" changes to the data. For example, even small station relocations can result in temperature readings that are either slightly cooler or slightly warmer than what would have occurred at the former site. Other changes, such as changes in urbanization in the vicinity of the station or changes in observing times can systematically affect temperatures, e.g., add an urban warming bias to the temperature trends. Research has shown that the data from these kinds of changes can be corrected to a large degree based on physical and statistical methods (e.g., see Peterson 2006).

Methods that have been used to correct temperature data is described in more than a dozen peer-reviewed scientific papers by NOAA's National Climatic Data Center (NCDC). A series of data corrections were developed to specifically address potential problems in trend estimation of the rates of warming or cooling in the USHCN. They include:

1. Station moves and instrumentation changes (Karl and Williams 1987, Quayle et al. 1991),
2. changes in observing practices, such as observing time changes (Karl et al. 1986), and
3. urbanization (Karl et al. 1988).

These data correction schemes have been applied to the USHCN to determine temperature trends across the United States up until the end of 2006. Beginning in 2007 improved correction schemes for items 1 and 3 above have been applied to the USHCN observations (Menne and Williams 2005, Menne and Williams 2007). They have been shown to improve our ability to monitor climate change and variations. Because different algorithms were used in making corrections to the station data in 2007 there are small

differences in annual average temperatures between the older corrections (Version 1) and newer Version 2 corrections. These small differences in average temperatures result in minor differences in annual rankings for some years. The new correction scheme has virtually no impact on the long-term temperature trend as annual temperature trends in Version 1 from 1895-2006 were 0.112°F/decade and in Version 2 the trends were 0.110°F/decade.

NOAA continues to work to improve the quality and representativeness of climate data provided to the public and scientific communities. In addition to advanced quality control procedures, these efforts include modernization of the USHCN by installing new, more accurate instrumentation and ensuring proper station siting in the process. In addition by the end of next year NOAA should have in place a U.S. Climate Reference Network, a set of 114 very high quality stations optimized for monitoring climate (<http://www.ncdc.noaa.gov/oa/climate/uscrn/>). The operation of the US Climate Reference Network will eventually virtually eliminate the need for the types of corrections that have to be applied to data available today. The ongoing modernization of the US Historical Climate Reference Network will enable trends of regional temperature to be estimated with far fewer data corrections.

At 01:52 PM 8/14/2007, Robert Cahalan wrote:

Jim,

Earlier I sent the following to Gavin -- and I realize that these are points you've been repeating for many years, just want to add that EarthObservatory could be helpful to get the word out:

Yes, I agree that this could be an educational opening for mainstream media.

My feeling is we need to lead with some of the faulty claims, and then illustrate that:

- (1) the data is all freely available and widely used for scientific study;
- (2) scientists use extensive statistical testing to determine whether observed differences can be ignored as being within the observational uncertainty or natural year-to-year variations;
- (3) changes of a given magnitude at a station or in a limited area average like the lower 48 contiguous United States, which covers about 2% Earth's surface, are less likely to be significant than a change of similar magnitude in averages over the full surface area of the Earth, which is less affected by many local influences (mention corrections to minimize urban effects too); and
- (4) changes in individual years, even ones that change the ranking of years, are less likely to be associated with sustained climate change than changes averaged over several successive years. On this last point we might quote the CCSP temperature synthesis and assessment product 1.1, which emphasized this point.

Of course these are all basic points that any of us climatologists know, but the public needs reminding, and this brouhaha could give a good opportunity to educate any "fence-sitters" who might be listening...

On Tue, 14 Aug 2007, David Herring wrote:

Hey Gavin,

I just left you voicemail, but also wanted to write to explore your availability to speak with me about the GISS temperature record. Bob Cahalan feels, and I agree, that given the recent turn of events it might be a good idea to educate the public

about how these data are gathered, and why it's actually harder to calculate average temperature for, say, the continental U.S. than it is for the whole globe.

Anyway, I can see the rightwing blogosphere is revving up into high gear now and so perhaps a report on NASA's Earth Observatory and seizing this opportunity to inform the public will steal most of the hot air out of their collective balloon, eh?

Please advise me on your availability to bring me up to speed. I think Bob C. would like to join us in that conversation as well.

best regards,

--

David Herring

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected by adding the NOAA/NCDC adjustment near the end of the record to the 2001-2007 data, and it has been so corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the *Washington Times* (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the *Spectator*, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Jack, I am writing something, with figures, which I will send later today. Here are a few relevant paragraphs for now. Jim

The computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001). The flaw affected temperatures only in the United States and only after 2000.

[As explained in the e-mail sent out last week, one of the improvements made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the United States as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day at which measurements were made, etc. Our computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in the temperature anomalies in 2000. This discontinuity can be removed by comparing USHCH and GHCN records just before 2000, and this correction was made to the GISS computer program on XX July 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

:On 8/14/07, Jack Kaye <jack.a.kaye@nasa.gov> wrote:

Jim - thanks for sending this to me.

We have an action to respond to a Congressional question about this. Can you provide us with a relatively straightforward answer (with some #) that we can transmit? I don't think we need anything extensive or complex, but a relatively brief (but quantitative) "just the facts" summary would help. As a backup, it may be good if we could have some # in case we get asked for more detail (e.g., list of top 20 warm years, time series of global T for last 15 years and also for 1934 +/- 5 years).

Don is on travel, but may be checking e-mail.

Time scale is, of course, asap! - Jack

[As explained in the e-mail sent out last week, one of the improvements made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the United States as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day at which measurements were made, etc. Our computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in the temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on XX July 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

On 8/14/07, Jack Kaye <jack.a.kaye@nasa.gov> wrote:

Jim - thanks for sending this to me.

We have an action to respond to a Congressional question about this. Can you provide us with a relatively straightforward answer (with some #) that we can transmit? I don't think we need anything extensive or complex, but a relatively brief (but quantitative) "just the facts" summary would help. As a backup, it may be good if we could have some # in case we get asked for more detail (e.g., list of top 20 warm years, time series of global T for last 15 years and also for 1934 +/- 5 years).

Don is on travel, but may be checking e-mail.

Time scale is, of course, asap! - Jack

On 8/14/07 2:52 AM, "James Hansen" <jhansen@giss.nasa.gov> wrote:

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it.

The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected by adding the NOAA/NCDC adjustment near the end of the record to the 2001-2007 data, and it has been so corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. *In an op-ed for the Washington Times (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.*

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com <<http://climateaudit.com/>> labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Subject: Re: 1997-2006 vs. 1880-1920 maps
From: "Makiko Sato" <makis@giss.nasa.gov>
Date: Wed, 15 Aug 2007 06:54:51 -0400
To: "James Hansen" <jhansen@giss.nasa.gov>
CC: "Reto Ruedy" <ruedy@giss.nasa.gov>

OK. As long as I can get wrong and corrected data in the same format from Reto, I can make these maps easily. As I showed on ~makis/GISSTemp, the corrected ones I get from Reto's web page and the ones I made map data using his old data look very different, and we cannot show them together.

First I thought any data are OK, but I am sure many will compare maps with our web site. So I know it is a lot of work for Reto as usual, but since it is getting more and more a serious problem (not scientifically at all but politically), I will ask him to put old data on a temporary web site so that I can get the map data using the old data from a web site in exactly the same manner as the new ones.

How soon do you need? I cannot come in Friday.

Makiko

On 8/15/07, James Hansen <jhansen@giss.nasa.gov> wrote:

I am now writing a new clear discussion of the whole matter (now that Congress and NASA management are involved). I would like the first figure to be the two figures that you made before (line graph of global T and line graph of U.S. T, showing the original and corrected results). These should be side by side, and thus smaller than before.

The other figure should be maps. I am only interested in land+ocean. By the way I cannot understand your 1934 vs 1998 maps. As you seem to be able to show three maps across very well, we might consider including 1934 and 1998 maps (land plus ocean in both cases). Here is the maps that I think we would like:

Column 1 "1997-2006 relative to 1880-1920"

Column 2 "1997-2006 relative to 1951-1980"

Column 3 "1934 versus 1998"

Heading for 1st and 2nd maps in top row: Flawed Data

Heading for 3rd map in top row: 1934 relative to 1951-1980

Heading for 1st and 2nd maps in 2nd row: Corrected Data

Heading for 3rd map in 2nd row: 1998 relative to 1951-1980

On second thought, maybe it is better to make the 4 maps that go together as a two-by-two figure, and then make a third figure with four parts 1934, 1998, and the two warmest U.S. years in 2000-2006.

Hi Phil,

Thanks, this is very helpful. Glad that you are keeping on top of these things -- we can only give a small fraction of our time to this topic, so it is good that someone keeps on top of it. By the time you are ready to retire global warming may be large enough that it doesn't require that level of expertise and detail. I am especially interested in your comments about NOAA SSTs -- they seemed just a hair cool to me.

Jim

On 8/15/07, Phil Jones <p.jones@uea.ac.uk> wrote:

> Jim, Gavin,

Your recent finding of NCDC/GHCN not continuing to adjust records in real time and its impacts on blog sites, has alerted me to inform you of a few things we've been doing over the past year. Don't pass any of this on via Real Climate or whatever. Eventually, we will get around to documenting all we've been doing.

1. You may have noticed that Canada has changed loads of its WMO IDs. We've been in contact with Lucie Vincent there who's also been doing some homogeneity work (which is good by the way). As a result of this we are applying adjustments in real time to about 40 stations (mainly in the east of the country) in order to use her long adjusted series. Why she adjusted records to an earlier period still isn't clear to me. We are also getting on top of their station number changes, which appear related to automation - and giving the new AWSs a new number.

By the way the AES web site enables you to get their real time data, but there is no mention there of another page which gives the homogeneous series!

This is all less important with your method of combination. Ours requires normals.

2. We're getting all Australian data in real time direct from the

National Climate Centre
in Melbourne.

3. We've got all the long NZ series they have homogenized.

Problems with both Australia and NZ associating these with WMO IDs we had.

Why it's always the English speaking countries is odd? Maybe this is because we can find out/understand more easily what they're doing!

4. My biggest worry is China. CMA don't measure at airports, and they keep moving suburban locations a few more miles out as the cities expand. I was there a month ago to give some talks. I've sent them all the CRU data for China, in the hope that they will reciprocate at some point and send me their adjusted data (for site moves, but not urban influences).

They are doing some reasonable work, but not seeing the big picture...

Other issues:

1. I reviewed a paper by NCDC (Smith/Reynolds/Peterson) recently. It was OK, but when it comes out it will raise the whole debate again. SSTs are being increasingly measured by buoys (drifting and fixed) and they now dominate over the ships. It seems they are about 0.1-0.2C cooler over the ships. So NCDC will be increasing global temps from about 2000 onwards.

2. SSTs are now coming in for the areas losing Arctic sea ice. The normals we have for these are -1.8C which is completely wrong. Shortish time series are composed of entirely positive anomalies. Maybe this is true, but it probably shouldn't be as much as it is. This problem will get worse as the sea ice continues to go. Your use of land only data shouldn't have the problem.

The SST issues highlight that it is the biases (bucket/intakes and urbanization) that are important as they are potentially pervasive. Individual station homogeneity issues cancel as sites are all affected differently. Getting this right has hardly any effect (none in fact) on the large-scale averages. Might affect smaller regions, and it's good to get as many right as possible, as the deniers will claim if one is wrong the whole lot is wrong. The law of large numbers seems to be totally forgotten by those collecting pictures of sitings across the US. Still it gives them something to do...

Cheers
Phil

Subject: Usufruct and the Gorilla

From: "James Hansen" <jhansen@giss.nasa.gov>

Date: Wed, 15 Aug 2007 13:44:13 -0400

To: "Makiko Sato" <makis@giss.nasa.gov>, "Reto Ruedy" <cdrar@giss.nasa.gov>

CC: "Robert B. Schmunk" <rschmunk@giss.nasa.gov>

Maybe you should read the first part of this story to make sure there are no errors.

Robert, if you get this e-mail: would you be available later today to put this story (to be in an e-mail) on the Columbia web site? Or can you give directions for someone else to do that?

Jim

The Real Deal: Usufruct & the Gorilla

Fox, Washington Times, and their like have gone bananas over a flaw discovered in the computer program that produces a global temperature map at GISS each month. They have even managed to get Congress and NASA Headquarters involved. Now we know what mom meant when she said "don't make a federal case out of it". Hey, what is really going on here?

The said computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001). The flaw affected temperatures only in the United States (by just over a tenth of a degree) and only after 2000. We made the adjustment to the program, thanked the fellow who pointed it out, and thought that was the end of it.

[The correction: As explained in the e-mail sent last week, one improvement made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the U.S. as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day of temperature measurements, etc. Our computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program instead picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in temperature anomalies in 2000. This discontinuity can be removed by comparing USHCH and GHCN records just before 2000, and this correction was made to the GISS computer program on XX July 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

Figure 1. Global (a) and U.S. (b) before and after correction of flaw in computer program.

What we have here is a case of dogged contrarians who present results in ways intended to deceive the public into believing that the changes have greater significance than reality. They aim to make a mountain out of a mole hill. I believe that these people are not stupid, instead they are seeking to create a brouhaha and muddy the waters in the climate change story. They seem to know exactly what they are doing and believe they can get away with it, because the public does not have the time, inclination, and training to discern what is a significant change with regard to the global warming issue.

The proclamations of the contrarians are a deceit, but their story raises a much more important

matter, usufruct. It is the most important issue in the entire global warming story, in my opinion. The players in the present U.S. temperature story, we scientists included, are just bit players. The characters in the main drama are big fish, really big fish. But before we get to that crucial matter, I need to make clear how the deceit of the little fish works, to expose their sham.

Instead of showing the impact of the flaw in our analysis program via a graph such as Figure 1, as a scientist would do (and as would immediately reveal how significant the flaw was), they instead choose to discuss the ranking of temperature in different years. We have thus been besieged by journalists saying "they say that correcting your error caused the warmest year to become 1934 rather than a recent year, is that right!?"

Hardly. First of all, many journalists had the impression that they were talking about global temperature. As you can see from Figure 1a, global warming is unaffected by the flaw. This realization should be enough to make most journalists lose interest, as global warming refers to global temperature.

But what if you are a chauvinist and only care about temperature in the United States? Did correcting the flaw in the program change the time of calculated maximum temperature to 1934? No. If you look at our 2001 paper, and get out your micrometer, you will see that we found 1934 to be the warmest year in the United States, by a hair, of the order of 0.01°C warmer than 1998, the same as the result that we find now. Of course the difference in the 1934 and 1998 temperatures is not significant, and we made clear in our paper that such years have to be declared as being practically a dead-heat.

Indeed, when we receive new data each month, which often adds in new stations, or modifies the results at a small number of stations, the results for a given year can fluctuate as much as a few hundredths of a degree. Also the GISS ranking is commonly different than that obtained in the NOAA or British analyses. This is expected, as there are significant differences in the methods. For example, the urban warming that we estimate (and remove) is larger than that used by the other groups.

there must be something wrong with the second sentence -- please reread it Reto. Jim

On 8/15/07, lesqiss@verizon.net <lesqiss@verizon.net> wrote:

Thanks, Reto.

I spoke with Tabatha again..she said Jack Kaye suggested adding the details that the changes were to US stations only, and only post-2000...

Jim--if Reto's revisions, and Jack's are okay, please let me know.

Leslie

Here is my suggested revision:

Researchers at NASA's Goddard Institute for Space Studies in New York recently revised information on their global temperature record based on corrected data. The program that replaced for some US stations the 1880-1999 record by records that were adjusted for instrumentation and procedural changes, used the original source for the later years without modifying them to fit the adjusted data. The result was a discontinuity in year 2000 for the US stations involved. Since the necessary adjustment was positive for about half the stations and negative for the other half, the effect on US means was a discontinuity of +.15C, and of .003C for the global mean series. The researchers ...

It becomes clearer if we split that sentence into 2 sentences:

The flawed program replaced for some US stations the 1880-1999 record by records adjusted for instrumentation and procedural changes, as it was supposed to. However, it used the original source for the years after 1999 without modifying them to fit the adjusted data. The result was ...

Sorry for the long complicated sentence,
Hope that makes it better.

The Real Deal: Usufruct & the Gorilla

Fox, Washington Times, and their like have gone bananas over a flaw discovered in the computer program that produces global temperatures at GISS each month. They have even managed to get Congress and NASA Headquarters involved. Now we know what mom meant when she said "don't make a federal case out of it". Hey, what is really going on here?

The said computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001) http://pubs.giss.nasa.gov/docs/2001/2001_Hansen_et_al.pdf The flaw affected temperatures only in the United States (by about 0.15°C) and only in 2000 and later. We corrected the flaw in the program, thanked the fellow who pointed it out, and thought that was the end of it.

[The correction: As explained in the e-mail sent last week, http://www.columbia.edu/~jeh1/distro_LightUpstairs_70810.pdf one improvement made in our 2001 analysis was to use USHCN (U.S. Historical Climatology Network) station records in the U.S. as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day of temperature measurements, etc. Our computer program presumed that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program instead picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

What we have here is a case of dogged contrarians who present results in ways intended to deceive the public into believing that the changes have greater significance than reality. They aim to make a mountain out of a mole hill. I believe that these people are not stupid, instead they

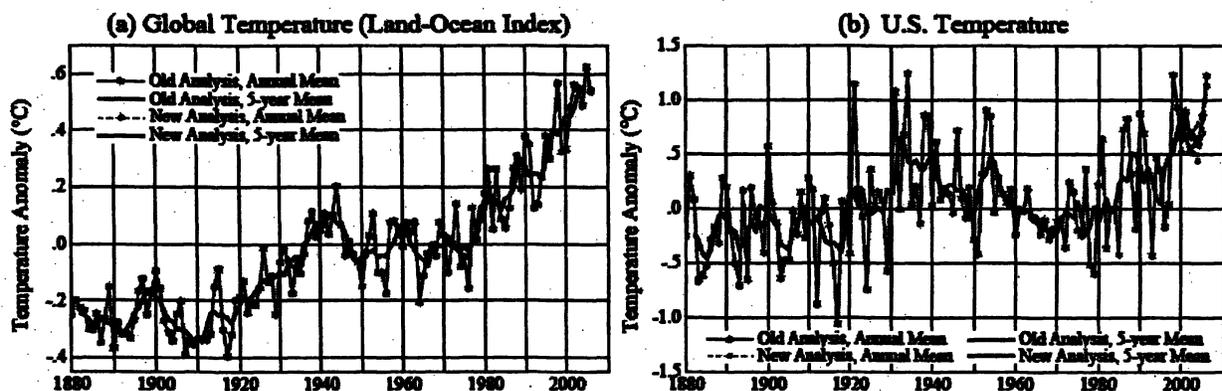

Figure 1. Global (a) and U.S. (b) before and after correction of flaw in computer program.

seek to create a brouhaha and muddy the waters in the climate change story. They seem to know exactly what they are doing and believe they can get away with it, because the public does not have the time, inclination, and training to discern what is a significant change with regard to the global warming issue.

The proclamations of the contrarians are a deceit, but their story raises a more important matter, usufruct. It is the most important issue in the entire global warming story, in my opinion. The players in the present U.S. temperature story, we scientists included, are just bit players. The characters in the main drama are big fish, really big fish. But before we get to that matter, I need to expose how the deceit works.

Instead of showing the impact of the flaw in our analysis program via a graph such as Figure 1, as a scientist would do (and as would immediately reveal how significant the flaw was), they instead discuss ranking of temperature in different years, including many false statements. We have thus been besieged by journalists saying "they say that correcting your error caused the warmest year to become 1934 rather than a recent year, is that right!?"

Hardly. First of all, many journalists had the impression that they were talking about global temperature. As you can see from Figure 1a, global warming is unaffected by the flaw. This realization should be enough to make most journalists lose interest, as global warming refers to global temperature.

But what if you are a chauvinist and only care about temperature in the United States? Did correcting the flaw in the program change the time of calculated maximum temperature to 1934? No. If you look at our 2001 paper, and get out your micrometer, you will see that we found 1934 to be the warmest year in the United States, by a hair, of the order of 0.01°C warmer than 1998, the same as the result that we find now. Of course the difference in the 1934 and 1998 temperatures is not significant, and we made clear in our paper that such years have to be declared as being practically a dead-heat.

Indeed, when we receive new data each month, which often adds in new stations, or modifies the results at a small number of stations, the results for a given year can fluctuate as much as a few hundredths of a degree. Also the GISS ranking of years is commonly different than that obtained from the NOAA or British analyses. This is expected, as there are significant differences in the methods. For example, the urban warming that we estimate (and remove) is larger than that used by the other groups (as discussed in 2001 Hansen et al. reference above).

Let's look (Figure 2) at the temperature anomalies in the four years that yield the warmest U.S. in our analysis. The U.S. mean temperature anomalies that we obtain range from 1.25°C in 1934 to 1.13°C in 2006. Thus the total range among these four years is just over a tenth of a degree. The uncertainty in the U.S. temperature is at least that large (see our published papers), so we can only say that these four years were comparably warm and the warmest year was probably either 1934 or 1998.

Note, however, that the 1998 and 2006 temperature anomaly maps differ fundamentally from the 1934 and 1921 temperature maps. In 1998 and 2006 the world as a whole has become warmer, 1998 being aided by a very strong El Nino, but 2006 by only a very weak El Nino. In 1921 and 1934 the United States happened to be a relatively hot spot compared to the world as a whole. The next time that the U.S. temperature happens to be unusually high relative to the globe, it may be quite a barn burner.

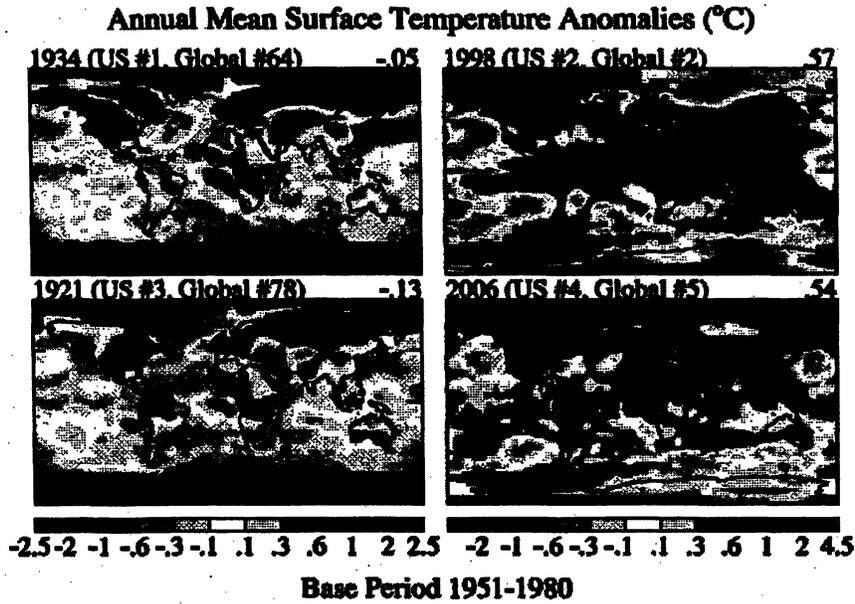

Figure 2. Temperature anomalies, relative to 1951-1980 base period, in the four years that are the warmest in the contiguous U.S. in the GISS analysis.

Although the media is always very interested in the ranking of individual years, the precise ranking is not only difficult to define accurately, it is also less important than the climate change averaged over several years. Figure 3 shows surface temperature anomalies of the past 10 years relative to both a 1880-1920 base period and the usual 1951-1980 base period. The figure also shows these results both with and without the flaw in our temperature analysis.

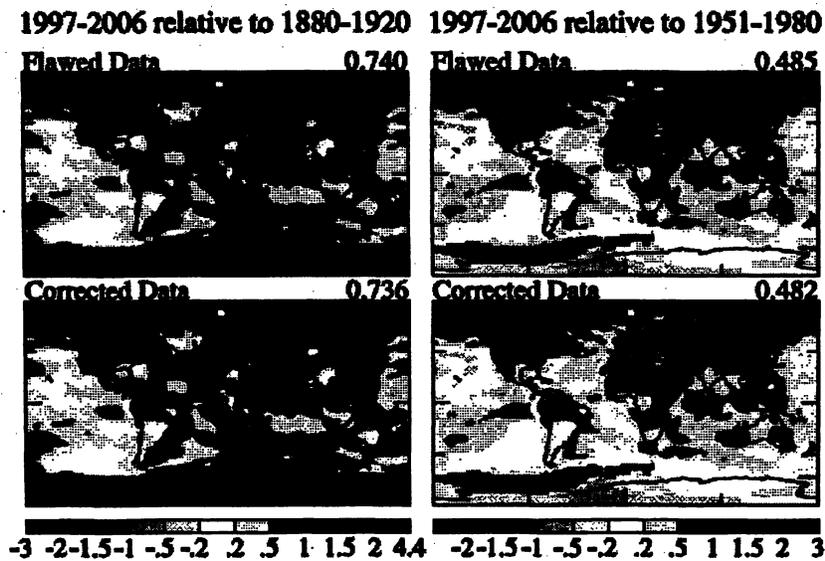

Figure 3. Surface temperature anomalies in the past 10 years (1997-2006) relative to two alternative base periods, 1880-1920 on the left and 1951-1980 on the right. The top row versus the bottom row shows the effect of the data flaw.

Over the past 30 years temperature isotherms have been moving poleward in the Northern Hemisphere land areas at a rate of about 50 km per decade. If the movements were fluctuations, their impacts would be limited. However, continual change of the same sense has a cumulative effect on the ability of species to survive in the presence of other stresses. Moreover, under business-as-usual growth of greenhouse gas emissions the rate of movement of isotherms could double this century, as discussed in several papers available on our web site, including "Dangerous" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_1.pdf "Trace Gases" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_2.pdf

Implications of this rapid and growing global climate change are discussed in "The 800 Pound Gorilla: The Threat and Taming of Global Climate Change",

"Gorilla" <http://www.giss.nasa.gov/~jhansen/preprints/>

"Gorilla" is adapted from "The Threat to the Planet" (13 July 2006 New York Rev. Books) with assistance of Walter Simpson. "Gorilla" includes sidebars on 'Likely Consequences of Global Climate Change' and 'Three Policies Needed to Defuse the Global Warming Time Bomb'.

Usufruct. The deceit behind the attempts to discredit evidence of climate change reveals matters of importance. This deceit has a clear purpose: to confuse the public about the status of knowledge of global climate change, thus delaying effective action to mitigate climate change. The danger is that delay will cause tipping points to be passed, such that large climate impacts become inevitable, including the loss of all Arctic sea ice, destabilization of the West Antarctic ice sheet with disastrous sea level rise later this century, and extermination of a large fraction of animal and plant species (see "Dangerous", "Trace Gases", and "Gorilla" papers).

Make no doubt, however, if tipping points are passed, if we, in effect, destroy Creation, passing on to our children, grandchildren, and the unborn a situation out of their control, the contrarians who work to deny and confuse will not be the principal culprits. The contrarians will be remembered as court jesters. There is no point to joust with court jesters. They will always be present. They will continue to entertain even if the Titanic begins to take on water. Their role and consequence is only as a diversion from what is important.

The real deal is this: the 'royalty' controlling the court, the ones with the power, the ones with the ability to make a difference, with the ability to change our course, the ones who will live in infamy if we pass the tipping points, are the captains of industry, CEOs in fossil fuel companies such as EXXON/Mobil, automobile manufacturers, utilities, all of the leaders who have placed short-term profit above the fate of the planet and the well-being of our children. The court jesters are their jesters, occasionally paid for services, and more substantively supported by the captains' disinformation campaigns.

Court jesters serve as a distraction, a distraction from usufruct. Usufruct is the matter that the captains wish to deny, the matter that they do not want their children to know about. They realize that if there is no 'gorilla', then usufruct is not an important issue for them. So, with the help of jesters, they deny the existence of the gorilla. There is no danger of melting the Arctic, of destabilizing the West Antarctic ice sheet, of increasing hydrologic extremes, more droughts and stronger forest fires on one hand and heavier downpours and floods on the other, threats to the fresh water supplies of huge numbers of people in different parts of the globe.

"Whew! It is lucky that, as our jesters show, these are just imaginary concerns. We captains of industry can continue with business-as-usual, we do not need to face the tough problem of how to maintain profits without destroying our legacy in our children's eyes."

Usufruct is as American as the Declaration of Independence, implicit in the Preamble "...to ourselves and our Posterity...". It is explicitly discussed in a famous letter of 6 September

1789 from Thomas Jefferson to James Madison, discussing the proposed Bill of Rights to be added to the Constitution: "The question whether one generation of men has a right to bind another. . . is a question of such consequences as not only to merit decision, but place also among the fundamental principles of every government. . . . I set out on this ground, which I suppose to be self-evident, 'that the Earth belongs in usufruct to the living' . . ."

Jefferson's philosophy regarding generational relations was based on this "self-evident" principle. That we have an obligation to preserve Creation for today's and future generations is a widely held belief. Native American Oren Lyons, a Faithkeeper in the Onondaga Nation, discusses the belief of Native Americans in their obligations to the "seventh generation". It is also a biblical paradigm that the Earth, Creation, is an intergenerational commons, the fruits and benefits of which should be accessible to every member of every generation.

Is the principle that the Earth belongs to us only in usufruct indeed self-evident and accepted by the public? In "Gorilla" I note the observation of Larry King that "nobody cares about 50 years from now". We can't take both positions. We need to make up our mind. Do we care?

I am puzzled by views expressed by some conservatives, views usually expressed in vehement unpleasant ways in e-mails that I have been bombarded by in the past several days. It is a bit disconcerting as I come from a moderately conservative state, and I consider myself a moderate conservative in most ways. It is puzzling, because it seems to me that conservatives should be the first ones standing up for preserving Creation, and for the rights of the young and the unborn. That is the basic intergenerational issue in global warming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

Is it possible that conservatives have been too quick to support the captains of industry? If we allow industry to continue on a path of denial, to focus on their short-term profits, to deny the rights of our children, grandchildren and the unborn, if the planet passes climate tipping points, will we not share in the infamy, the infamy of the captains of industry?

It seems to me that the present situation, with only minimalist actions to mitigate global climate change, reflects, at least in part, the "success" of the disinformation campaign that the captains of industry have at least tolerated, and, in some cases, encouraged and supported. Of course Nature will, eventually, reveal the truth, but there is potentially great harm in the disinformation, because it increases the likelihood that we will pass climate tipping points.

The captains of industry are smarter than their jesters. They cannot pretend that they are unaware of climate change dangers and consequences for future generations. It is time for the captains of industry to rethink their positions. I do not mean, time to polish their image with marginal investments, 'green' advertisements, and other public relations gimmicks. I mean, time to consider how they will function as we move toward a cleaner world 'beyond petroleum', to invest in approaches that will help take us from here to there, and to begin to move smartly in that direction. There is still time to avert the most dramatic climate effects, if we promptly begin to address both CO₂ and non-CO₂ climate forcings. But just barely.

I am indebted to Jim Wine for schooling me in 'usufruct'.

Criticisms, as always, are welcome.

The Real Deal: Usufruct & the Gorilla

Fox, Washington Times, and their like have gone bananas over a flaw discovered in the computer program that produces global temperatures at GISS each month. They have even managed to get Congress and NASA Headquarters involved. Now we know what mom meant when she said "don't make a federal case out of it". Hey, what is really going on here?

The said computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001)

http://pubs.giss.nasa.gov/docs/2001/2001_Hansen_etal.pdf The flaw affected temperatures only in the United States (by about 0.15°C) and only in 2000 and later. We corrected the flaw in the program, thanked the fellow who pointed it out, and thought that was the end of it.

[The correction: As explained in the e-mail sent last week,

http://www.columbia.edu/~jeh1/distro_LightUpstairs_70810.pdf

one improvement made in our 2001 analysis was to use USHCN (U.S. Historical Climatology Network) station records in the U.S. as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day of temperature measurements, etc. Our computer program presumed that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program instead picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

What we have here is a case of dogged contrarians who present results in ways intended to deceive the public into believing that the changes have greater significance than reality. They aim to make a mountain out of a mole hill. I believe that these people are not stupid, instead they

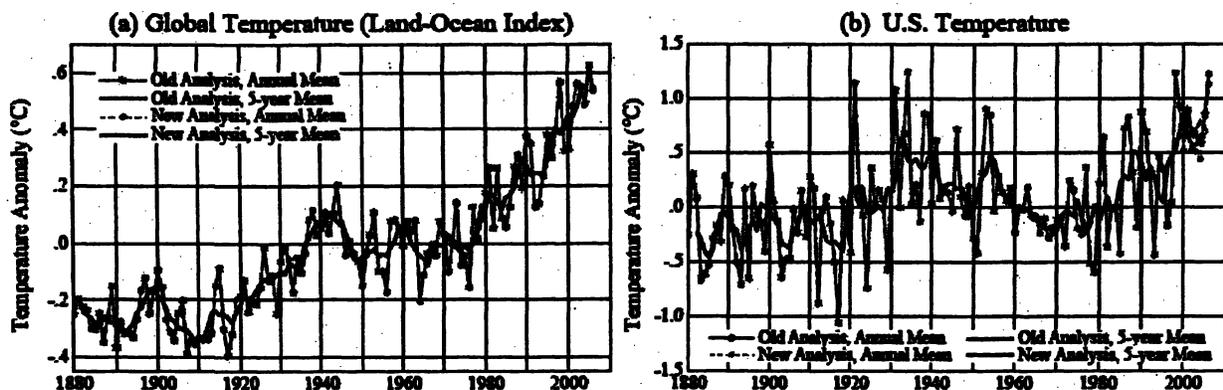

Figure 1. Global (a) and U.S. (b) before and after correction of flaw in computer program.

seek to create a brouhaha and muddy the waters in the climate change story. They seem to know exactly what they are doing and believe they can get away with it, because the public does not have the time, inclination, and training to discern what is a significant change with regard to the global warming issue.

The proclamations of the contrarians are a deceit, but their story raises a more important matter, usufruct. It is the most important issue in the entire global warming story, in my opinion. The players in the present U.S. temperature story, we scientists included, are just bit players. The characters in the main drama are big fish, really big fish. But before we get to that matter, I need to expose how the deceit works.

Instead of showing the impact of the flaw in our analysis program via a graph such as Figure 1, as a scientist would do (and as would immediately reveal how significant the flaw was), they instead discuss ranking of temperature in different years, including many false statements. We have thus been besieged by journalists saying "they say that correcting your error caused the warmest year to become 1934 rather than a recent year, is that right!?"

Hardly. First of all, many journalists had the impression that they were talking about global temperature. As you can see from Figure 1a, global warming is unaffected by the flaw. This realization should be enough to make most journalists lose interest, as global warming refers to global temperature.

But what if you are a chauvinist and only care about temperature in the United States? Did correcting the flaw in the program change the time of calculated maximum temperature to 1934? No. If you look at our 2001 paper, and get out your micrometer, you will see that we found 1934 to be the warmest year in the United States, by a hair, of the order of 0.01°C warmer than 1998, the same as the result that we find now. Of course the difference in the 1934 and 1998 temperatures is not significant, and we made clear in our paper that such years have to be declared as being practically a dead-heat.

Indeed, when we receive new data each month, which often adds in new stations, or modifies the results at a small number of stations, the results for a given year can fluctuate as much as a few hundredths of a degree. Also the GISS ranking of years is commonly different than that obtained from the NOAA or British analyses. This is expected, as there are significant differences in the methods. For example, the urban warming that we estimate (and remove) is larger than that used by the other groups (as discussed in 2001 Hansen et al. reference above).

Let's look (Figure 2) at the temperature anomalies in the four years that yield the warmest U.S. in our analysis. The U.S. mean temperature anomalies that we obtain range from 1.25°C in 1934 to 1.13°C in 2006. Thus the total range among these four years is just over a tenth of a degree. The uncertainty in the U.S. temperature is at least that large (see our published papers), so we can only say that these four years were comparably warm and the warmest year was probably either 1934 or 1998.

Note, however, that the 1998 and 2006 temperature anomaly maps differ fundamentally from the 1934 and 1921 temperature maps. In 1998 and 2006 the world as a whole has become warmer, 1998 being aided by a very strong El Nino, but 2006 by only a very weak El Nino. In 1921 and 1934 the United States happened to be a relatively hot spot compared to the world as a whole. The next time that the U.S. temperature happens to be unusually high relative to the globe, it may be quite a barn burner.

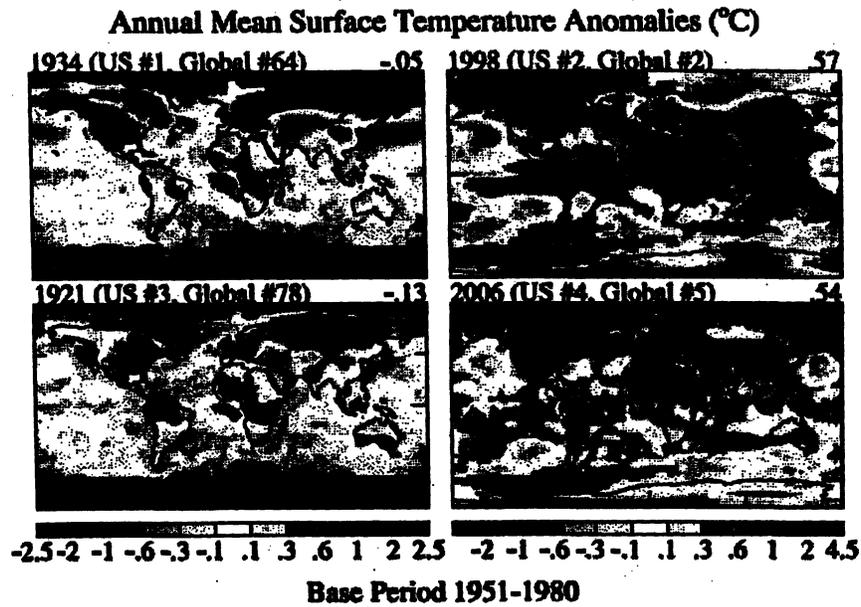

Figure 2. Temperature anomalies, relative to 1951-1980 base period, in the four years that are the warmest in the contiguous U.S. in the GISS analysis.

Although the media is always very interested in the ranking of individual years, the precise ranking is not only difficult to define accurately, it is also less important than the climate change averaged over several years. Figure 3 shows surface temperature anomalies of the past 10 years relative to both a 1880-1920 base period and the usual 1951-1980 base period. The figure also shows these results both with and without the flaw in our temperature analysis.

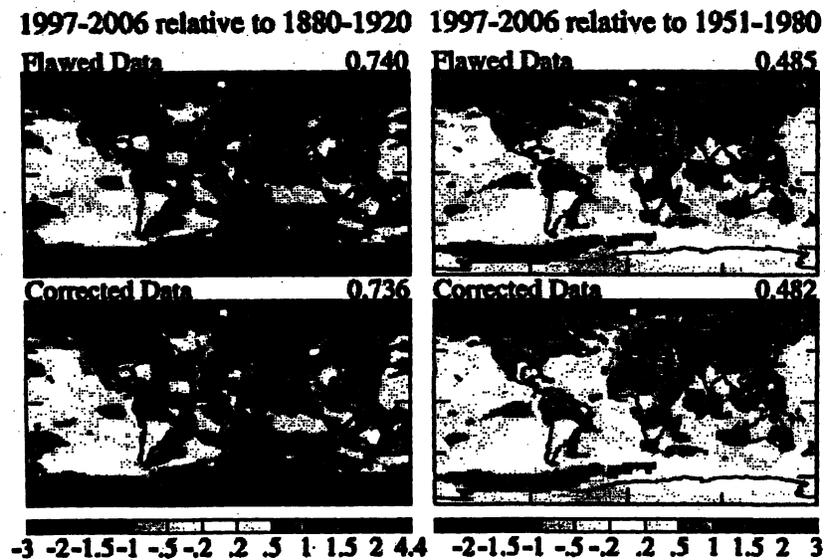

Figure 3. Surface temperature anomalies in the past 10 years (1997-2006) relative to two alternative base periods, 1880-1920 on the left and 1951-1980 on the right. The top row versus the bottom row shows the effect of the data flaw.

Over the past 30 years temperature isotherms have been moving poleward in the Northern Hemisphere land areas at a rate of about 50 km per decade. If the movements were fluctuations, their impacts would be limited. However, continual change of the same sense has a cumulative effect on the ability of species to survive in the presence of other stresses. Moreover, under business-as-usual growth of greenhouse gas emissions the rate of movement of isotherms could double this century, as discussed in several papers available on our web site, including "Dangerous" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_1.pdf "Trace Gases" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_2.pdf

Implications of this rapid and growing global climate change are discussed in "The 800 Pound Gorilla: The Threat and Taming of Global Climate Change",

"Gorilla" <http://www.giss.nasa.gov/~jhansen/preprints/>

"Gorilla" is adapted from "The Threat to the Planet" (13 July 2006 New York Rev. Books) with assistance of Walter Simpson. "Gorilla" includes sidebars on 'Likely Consequences of Global Climate Change' and 'Three Policies Needed to Defuse the Global Warming Time Bomb'.

Usufruct. The deceit behind the attempts to discredit evidence of climate change reveals matters of importance. This deceit has a clear purpose: to confuse the public about the status of knowledge of global climate change, thus delaying effective action to mitigate climate change. The danger is that delay will cause tipping points to be passed, such that large climate impacts become inevitable, including the loss of all Arctic sea ice, destabilization of the West Antarctic ice sheet with disastrous sea level rise later this century, and extermination of a large fraction of animal and plant species (see "Dangerous", "Trace Gases", and "Gorilla" papers).

Make no doubt, however, if tipping points are passed, if we, in effect, destroy Creation, passing on to our children, grandchildren, and the unborn a situation out of their control, the contrarians who work to deny and confuse will not be the principal culprits. The contrarians will be remembered as court jesters. There is no point to joust with court jesters. They will always be present. They will continue to entertain even if the Titanic begins to take on water. Their role and consequence is only as a diversion from what is important.

The real deal is this: the 'royalty' controlling the court, the ones with the power, the ones with the ability to make a difference, with the ability to change our course, the ones who will live in infamy if we pass the tipping points, are the captains of industry, CEOs in fossil fuel companies such as EXXON/Mobil, automobile manufacturers, utilities, all of the leaders who have placed short-term profit above the fate of the planet and the well-being of our children. The court jesters are their jesters, occasionally paid for services, and more substantively supported by the captains' disinformation campaigns.

Court jesters serve as a distraction, a distraction from usufruct. Usufruct is the matter that the captains wish to deny, the matter that they do not want their children to know about. They realize that if there is no 'gorilla', then usufruct is not an important issue for them. So, with the help of jesters, they deny the existence of the gorilla. There is no danger of melting the Arctic, of destabilizing the West Antarctic ice sheet, of increasing hydrologic extremes, more droughts and stronger forest fires on one hand and heavier downpours and floods on the other, threats to the fresh water supplies of huge numbers of people in different parts of the globe.

"Whew! It is lucky that, as our jesters show, these are just imaginary concerns. We captains of industry can continue with business-as-usual, we do not need to face the tough problem of how to maintain profits without destroying our legacy in our children's eyes."

Usufruct is as American as the Declaration of Independence, implicit in the Preamble

~~"...to ourselves and our Posterity...". It is explicitly discussed in a famous letter of 6 September~~

1789 from Thomas Jefferson to James Madison, discussing the proposed Bill of Rights to be added to the Constitution: "The question whether one generation of men has a right to bind another. . . is a question of such consequences as not only to merit decision, but place also among the fundamental principles of every government. . . . I set out on this ground, which I suppose to be self-evident, 'that the Earth belongs in usufruct to the living' . . ."

Jefferson's philosophy regarding generational relations was based on this "self-evident" principle. That we have an obligation to preserve Creation for today's and future generations is a widely held belief. Native American Oren Lyons, a Faithkeeper in the Onondaga Nation, discusses the belief of Native Americans in their obligations to the "seventh generation". It is also a biblical paradigm that the Earth, Creation, is an intergenerational commons, the fruits and benefits of which should be accessible to every member of every generation.

Is the principle that the Earth belongs to us only in usufruct indeed self-evident and accepted by the public? In "Gorilla" I note the observation of Larry King that "nobody cares about 50 years from now". We can't take both positions. We need to make up our mind. Do we care?

I am puzzled by views expressed by some conservatives, views usually expressed in vehement unpleasant ways in e-mails that I have been bombarded by in the past several days. It is a bit disconcerting as I come from a moderately conservative state, and I consider myself a moderate conservative in most ways. It is puzzling, because it seems to me that conservatives should be the first ones standing up for preserving Creation, and for the rights of the young and the unborn. That is the basic intergenerational issue in global warming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

Is it possible that conservatives have been too quick to support the captains of industry? If we allow industry to continue on a path of denial, to focus on their short-term profits, to deny the rights of our children, grandchildren and the unborn, if the planet passes climate tipping points, will we not share in the infamy, the infamy of the captains of industry?

It seems to me that the present situation, with only minimalist actions to mitigate global climate change, reflects, at least in part, the "success" of the disinformation campaign that the captains of industry have at least tolerated, and, in some cases, encouraged and supported. Of course Nature will, eventually, reveal the truth, but there is potentially great harm in the disinformation, because it increases the likelihood that we will pass climate tipping points.

The captains of industry are smarter than their jesters. They cannot pretend that they are unaware of climate change dangers and consequences for future generations. It is time for the captains of industry to rethink their positions. I do not mean, time to polish their image with marginal investments, 'green' advertisements, and other public relations gimmicks. I mean, time to consider how they will function as we move toward a cleaner world 'beyond petroleum', to invest in approaches that will help take us from here to there, and to begin to move smartly in that direction. There is still time to avert the most dramatic climate effects, if we promptly begin to address both CO₂ and non-CO₂ climate forcings. But just barely.

Revised version suggested below. Jim

On 8/16/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

So here is an attempt to put the pieces together; I also adjusted the beginning and end to fit the other modifications; please don't hesitate to further improve my style:

Researchers at NASA's Goddard Institute for Space Studies in New York recently revised their global temperature record after correcting a step in their data acquisition procedure. The prior process appropriately replaced some US station records with records adjusted for instrumental and procedural changes. However, it reverted to the unadjusted data after 1999, the last year for which the adjusted data were available. This resulted in a discontinuity in year 2000 for the US stations involved. The adjustments necessary to remove the discontinuity turned out to be positive for about half the stations and negative for the other half. The net effect of the prior flaw was to increase the mean US temperature by about 0.15C and global temperature by about 0.003C, changes that were within the margin of error. The researchers corrected the computer program and posted their revised data on 7 August 2007. More information is available here: (LINK TO GISS SITE).

The Real Deal: Usufruct & the Gorilla

Fox, Washington Times, and their like have gone bananas over a flaw discovered in the computer program that produces global temperatures at GISS each month. They have even managed to get Congress and NASA Headquarters involved. Now we know what mom meant when she said "don't make a federal case out of it". Hey, what is really going on here?

The said computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001) http://pubs.giss.nasa.gov/docs/2001/2001_Hansen_etal.pdf The flaw affected temperatures only in the United States (by about 0.15°C) and only in 2000 and later. We corrected the flaw in the program, thanked the fellow who pointed it out, and thought that was the end of it.

[The correction: As explained in the e-mail sent last week, http://www.columbia.edu/~jeh1/distro_LightUpstairs_70810.pdf one improvement made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the U.S. as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day of temperature measurements, etc. Our computer program presumed that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program instead picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

What we have here is a case of dogged contrarians who present results in ways intended to deceive the public into believing that the changes have greater significance than reality. They aim to make a mountain out of a mole hill. I believe that these people are not stupid, instead they

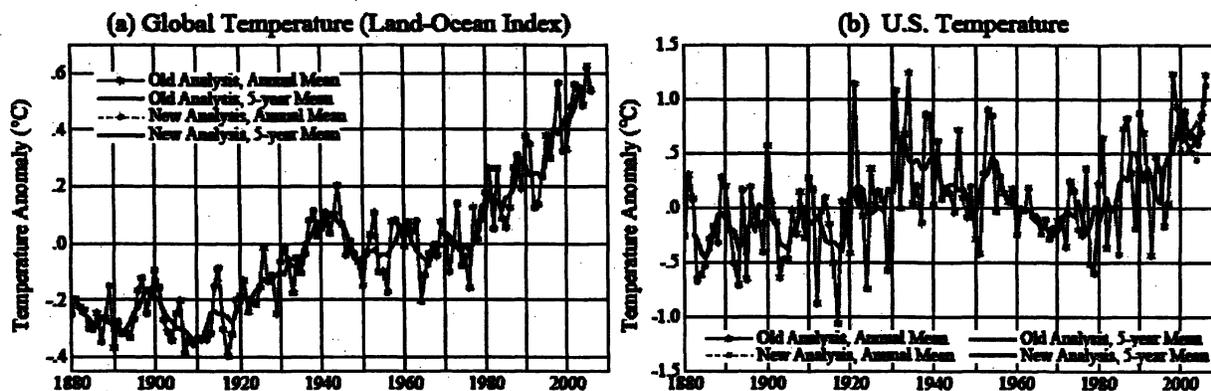

Figure 1. Global (a) and U.S. (b) before and after correction of flaw in computer program.

seek to create a brouhaha and muddy the waters in the climate change story. They seem to know exactly what they are doing and believe they can get away with it, because the public does not have the time, inclination, and training to discern what is a significant change with regard to the global warming issue.

The proclamations of the contrarians are a deceit, but their story raises a more important matter, usufruct. It is the most important issue in the entire global warming story, in my opinion. The players in the present U.S. temperature story, we scientists included, are just bit players. The characters in the main drama are big fish, really big fish. But before we get to that matter, I need to expose how the deceit works.

Instead of showing the impact of the flaw in our analysis program via a graph such as Figure 1, as a scientist would do (and as would immediately reveal how significant the flaw was), they instead discuss ranking of temperature in different years, including many false statements. We have thus been besieged by journalists saying "they say that correcting your error caused the warmest year to become 1934 rather than a recent year, is that right!?"

Hardly. First of all, many journalists had the impression that they were talking about global temperature. As you can see from Figure 1a, global warming is unaffected by the flaw. This realization should be enough to make most journalists lose interest, as global warming refers to global temperature.

But what if you are a chauvinist and only care about temperature in the United States? Did correcting the flaw in the program change the time of calculated maximum temperature to 1934? No. If you look at our 2001 paper, and get out your micrometer, you will see that we found 1934 to be the warmest year in the United States, by a hair, of the order of 0.01°C warmer than 1998, the same as the result that we find now. Of course the difference in the 1934 and 1998 temperatures is not significant, and we made clear in our paper that such years have to be declared as being practically a dead-heat.

Indeed, when we receive new data each month, which often adds in new stations, or modifies the results at a small number of stations, the results for a given year can fluctuate as much as a few hundredths of a degree. Also the GISS ranking of years is commonly different than that obtained from the NOAA or British analyses. This is expected, as there are significant differences in the methods. For example, the urban warming that we estimate (and remove) is larger than that used by the other groups (as discussed in 2001 Hansen et al. reference above).

Let's look (Figure 2) at the temperature anomalies in the four years that yield the warmest U.S. in our analysis. The U.S. mean temperature anomalies that we obtain range from 1.25°C in 1934 to 1.13°C in 2006. Thus the total range among these four years is just over a tenth of a degree. The uncertainty in the U.S. temperature is at least that large (see our published papers), so we can only say that these four years were comparably warm and the warmest year was probably either 1934 or 1998.

Note, however, that the 1998 and 2006 temperature anomaly maps differ fundamentally from the 1934 and 1921 temperature maps. In 1998 and 2006 the world as a whole has become warmer, 1998 being aided by a very strong El Nino, but 2006 by only a very weak El Nino. In 1921 and 1934 the United States happened to be relatively hot spot compared to the world as a whole. The next time that the U.S. temperature happens to be unusually high relative to the globe, it may be quite a barn burner.

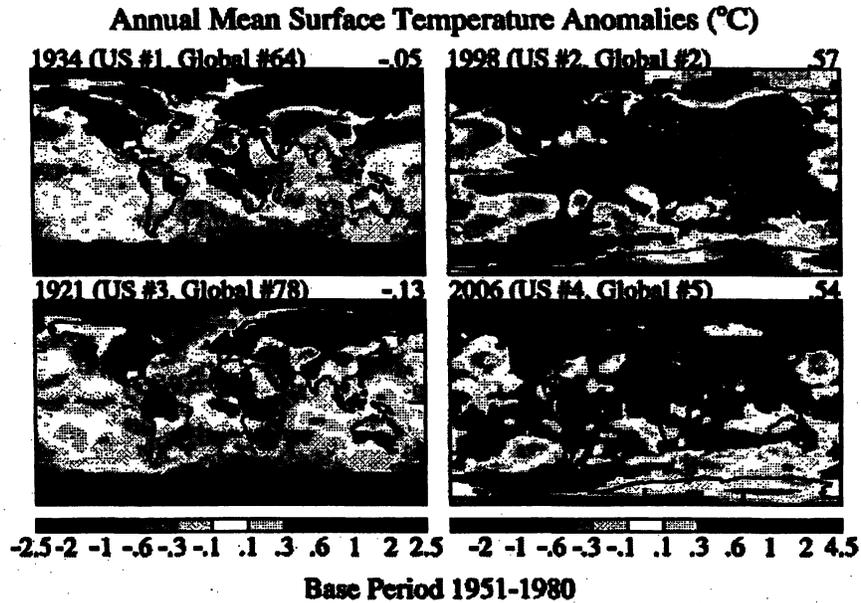

Figure 2. Temperature anomalies, relative to 1951-1980 base period, in the four years that are the warmest in the contiguous U.S. in the GISS analysis.

Although the media is always very interested in the ranking of individual years, the precise ranking is not only difficult to define accurately, it is also less important than the climate change averaged over several years. Figure 3 shows surface temperature anomalies of the past 10 years relative to both a 1880-1920 base period and the usual 1951-1980 base period. The figure also shows these results both with and without the flaw in our temperature analysis.

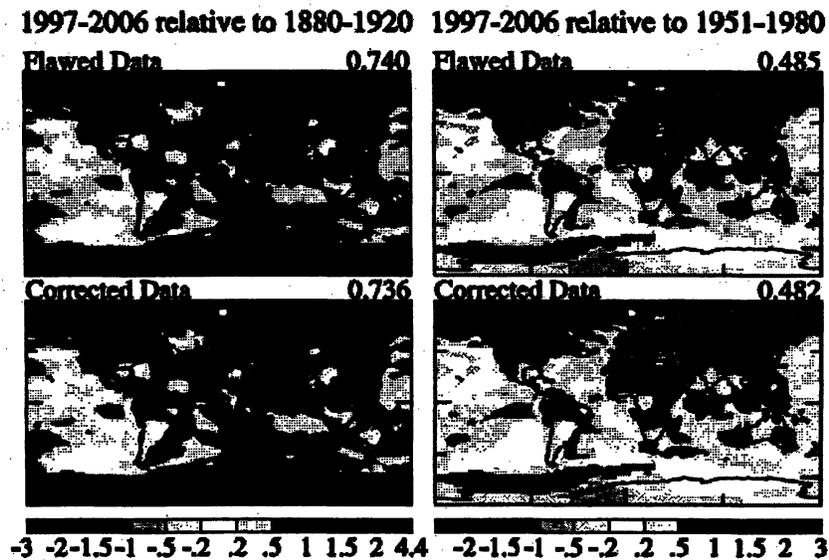

Figure 3. Surface temperature anomalies in the past 10 years (1997-2006) relative to two alternative base periods, 1880-1920 on the left and 1951-1980 on the right. The top row versus the bottom row shows the effect of the data flaw.

Over the past 30 years temperature isotherms have been moving poleward in the Northern Hemisphere land areas at a rate of about 50 km per decade. If the movements were fluctuations, their impacts would be limited. However, continual change of the same sense has a cumulative effect on the ability of species to survive in the presence of other stresses. Moreover, under business-as-usual growth of greenhouse gas emissions the rate of movement of isotherms could double this century, as discussed in several papers available on our web site, including "Dangerous" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_1.pdf "Trace Gases" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_2.pdf

Implications of this rapid and growing global climate change are discussed in "The 800 Pound Gorilla: The Threat and Taming of Global Climate Change",

"Gorilla" <http://www.giss.nasa.gov/~jhansen/preprints/Gorilla.070814.pdf>

"Gorilla" is adapted from "The Threat to the Planet" (13 July 2006 New York Rev. Books) with assistance of Walter Simpson. "Gorilla" includes sidebars on 'Likely Consequences of Global Climate Change' and 'Three Policies Needed to Defuse the Global Warming Time Bomb'.

Usufruct. The deceit behind the attempts to discredit evidence of climate change reveals matters of importance. This deceit has a clear purpose: to confuse the public about the status of knowledge of global climate change, thus delaying effective action to mitigate climate change. The danger is that delay will cause tipping points to be passed, such that large climate impacts become inevitable, including the loss of all Arctic sea ice, destabilization of the West Antarctic ice sheet with disastrous sea level rise later this century, and extermination of a large fraction of animal and plant species (see "Dangerous", "Trace Gases", and "Gorilla" papers).

Make no doubt, however, if tipping points are passed, if we, in effect, destroy Creation, passing on to our children, grandchildren, and the unborn a situation out of their control, the contrarians who work to deny and confuse will not be the principal culprits. The contrarians will be remembered as court jesters. There is no point to joust with court jesters. They will always be present. They will continue to entertain even if the Titanic begins to take on water. Their role and consequence is only as a diversion from what is important.

The real deal is this: the 'royalty' controlling the court, the ones with the power, the ones with the ability to make a difference, with the ability to change our course, the ones who will live in infamy if we pass the tipping points, are the captains of industry, CEOs in fossil fuel companies such as EXXON/Mobil, automobile manufacturers, utilities, all of the leaders who have placed short-term profit above the fate of the planet and the well-being of our children. The court jesters are their jesters, occasionally paid for services, and more substantively supported by the captains' disinformation campaigns.

Court jesters serve as a distraction, a distraction from usufruct. Usufruct is the matter that the captains wish to deny, the matter that they do not want their children to know about. They realize that if there is no 'gorilla', than usufruct is not an important issue for them. So, with the help of jesters, they deny the existence of the gorilla. There is no danger of melting the Arctic, of destabilizing the West Antarctic ice sheet, of increasing hydrologic extremes, more droughts and stronger forest fires on the one hand and heavier downpours and floods on the other, threats to the fresh water supplies of huge numbers of people in different parts of the globe. "Whew! It is lucky that, as our jesters show, these are just imaginary concerns. We captains of industry can continue with business-as-usual, we do not need to face the tough problem of how to maintain profits without destroying our legacy in our children's eyes."

Usufruct is as American as the Declaration of Independence, implicit in the Preamble

"...to ourselves and our Posterity...". It is explicitly discussed in a famous letter of 6 September

1789 from Thomas Jefferson to James Madison, discussing the proposed Bill of Rights to be added to the Constitution: "The question whether one generation of men has a right to bind another. . . is a question of such consequences as not only to merit decision, but place also among the fundamental principles of every government. . . . I set out on this ground, which I suppose to be self-evident, 'that the Earth belongs in usufruct to the living' . . ."

Jefferson's philosophy regarding generational relations was based on this "self-evident" principle. That we have an obligation to preserve Creation for today's and future generations is a widely held belief. Native American Oren Lyons, a Faithkeeper in the Onondaga Nation, discusses the belief of Native Americans in their obligations to the "seventh generation". It is also a biblical paradigm that the Earth, Creation, is an intergenerational commons, the fruits and benefits of which should be accessible to every member of every generation.

Is the principle that the Earth belongs to us only in usufruct indeed self-evident and accepted by the public? In "Gorilla" I note the observation of Larry King that "nobody cares about 50 years from now". We can't take both positions. We need to make up our mind.

I am puzzled by views expressed by some conservatives, views usually expressed in vehement unpleasant ways in e-mails that I have been bombarded by in the past several days. It is a bit disconcerting as I come from a moderately conservative state, and I consider myself a moderate conservative in most ways. It is puzzling, because it seems to me that conservatives should be the first ones standing up for preserving Creation, and for the rights of the young and the unborn. That is the basic intergenerational issue in global warming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

Is it possible that conservatives have been too quick to support the captains of industry? If we allow industry to continue on a path of denial, to focus on their short-term profits, to deny the rights of our children, grandchildren and the unborn, if the planet passes climate tipping points, will we not share in the infamy, the infamy of the captains of industry?

It seems to me that the present situation, with only minimalist actions to mitigate global climate change, reflects, at least in part, the "success" of the disinformation campaign that the captains of industry have at least tolerated, and, in some cases, encouraged and supported. Of course nature will, eventually, reveal the truth, but there is potentially great harm in the disinformation, because it increases the likelihood that we will pass climate tipping points.

The captains of industry are smarter than their jesters. They cannot pretend that they are unaware of climate change dangers and consequences for future generations. It is time for the captains of industry to rethink their positions. I do not mean, time to polish their image with marginal investments, 'green' advertisements, and other public relations gimmicks. I mean, time to consider how they will function as we move toward a cleaner world 'beyond petroleum', to invest in approaches that will help take us from here to there, and to begin to move smartly in that direction. There is still time to avert the most dramatic climate effects, if we promptly begin to address both CO₂ and non-CO₂ climate forcings. But just barely.

I am indebted to Jim Wine for schooling me in 'usufruct'.

Criticisms, as always, are welcome.

The Real Deal: Usufruct & the Gorilla

Fox, Washington Times, and their like have gone bananas over a flaw discovered in the computer program that produces global temperatures at GISS each month. They have even managed to get Congress and NASA Headquarters involved. Now we know what mom meant when she said "don't make a federal case out of it". Hey, what is really going on here?

The said computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001). The flaw affected temperatures only in the United States (by just over a tenth of a degree) and only in 2000 and later. We made the adjustment to the program, thanked the fellow who pointed it out, and thought that was the end of it.

[The correction: As explained in the e-mail sent last week, http://www.columbia.edu/~leh1/distro_LightUpstairs_70810.pdf one improvement made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the U.S. as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day of temperature measurements, etc. Our computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program instead picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

What we have here is a case of dogged contrarians who present results in ways intended to deceive the public into believing that the changes have greater significance than reality. They aim to make a mountain out of a mole hill. I believe that these people are not stupid, instead they

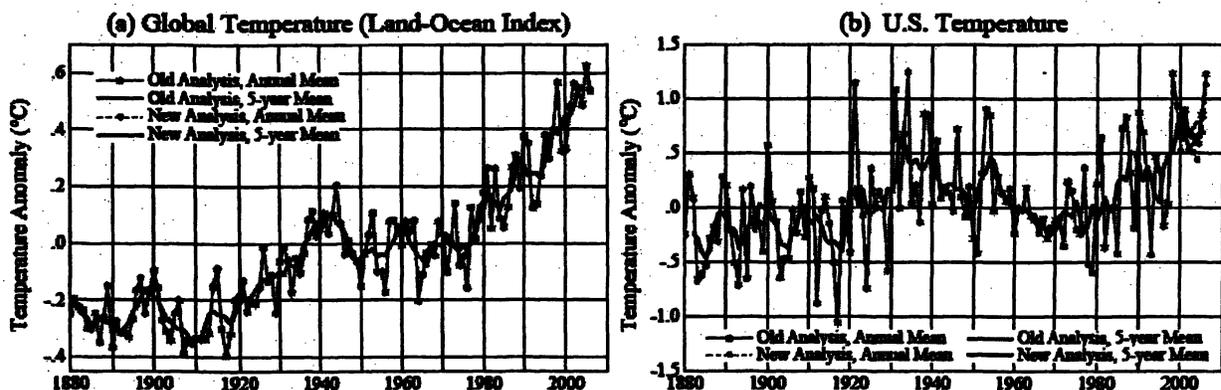

Figure 1. Global (a) and U.S. (b) before and after correction of flaw in computer program.

are seeking to create a brouhaha and muddy the waters in the climate change story. They seem to know exactly what they are doing and believe they can get away with it, because the public does not have the time, inclination, and training to discern what is a significant change with regard to the global warming issue.

The proclamations of the contrarians are a deceit, but their story raises a much more important matter, usufruct. It is the most important issue in the entire global warming story, in my opinion. The players in the present U.S. temperature story, we scientists included, are just bit players. The characters in the main drama are big fish, really big fish. But before we get to that crucial matter, I need to make clear how the deceit of the little fish works, to expose their sham.

Instead of showing the impact of the flaw in our analysis program via a graph such as Figure 1, as a scientist would do (and as would immediately reveal how significant the flaw was), they instead choose to discuss the ranking of temperature in different years. We have thus been besieged by journalists saying "they say that correcting your error caused the warmest year to become 1934 rather than a recent year, is that right!?"

Hardly. First of all, many journalists had the impression that they were talking about global temperature. As you can see from Figure 1a, global warming is unaffected by the flaw. This realization should be enough to make most journalists lose interest, as global warming refers to global temperature.

But what if you are a chauvinist and only care about temperature in the United States? Did correcting the flaw in the program change the time of calculated maximum temperature to 1934? No. If you look at our 2001 paper, and get out your micrometer, you will see that we found 1934 to be the warmest year in the United States, by a hair, of the order of 0.01°C warmer than 1998, the same as the result that we find now. Of course the difference in the 1934 and 1998 temperatures is not significant, and we made clear in our paper that such years have to be declared as being practically a dead-heat.

Indeed, when we receive new data each month, which often adds in new stations, or modifies the results at a small number of stations, the results for a given year can fluctuate as much as a few hundredths of a degree. Also the GISS ranking is commonly different than that obtained in the NOAA or British analyses. This is expected, as there are significant differences in the methods. For example, the urban warming that we estimate (and remove) is larger than that used by the other groups.

Let's look (Figure 2) at the temperature anomalies in the four years that yield the warmest U.S. in our analysis. The U.S. mean temperature anomalies that we obtain range from 1.25°C in 1934 to 1.13°C in 2006. Thus the total range among these four years is just over a tenth of a degree. The uncertainty in the U.S. temperature is at least that large (see our published papers), so we can only say that these four years were comparably warm and the warmest year was probably either 1934 or 1998.

Note, however, that the 1998 and 2006 temperature anomaly maps differ fundamentally from the 1934 and 1921 temperature maps. In 1998 and 2006 the world as a whole has become warmer, 1998 being aided by a very strong El Nino, but 2006 by only a very weak El Nino. In 1921 and 1934 the United States happened to be relatively hot spot compared to the world as a whole. The next time that the U.S. temperature happens to be unusually high relative to the globe, it may be quite a barn burner.

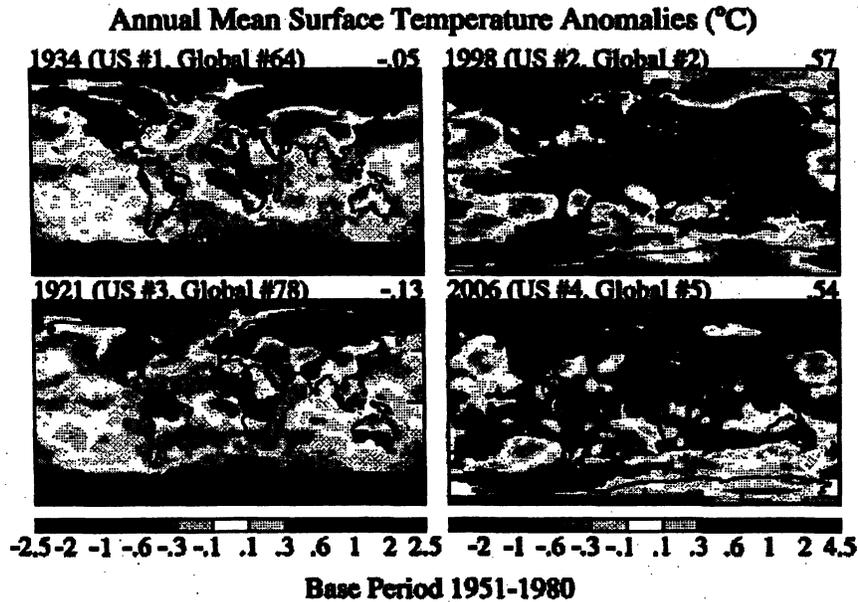

Figure 2. Temperature anomalies, relative to 1951-1980 base period, in the four years that are the warmest in the contiguous U.S. in the GISS analysis.

Although the media is always very interested in the ranking of individual years, the precise ranking is not only difficult to define accurately, it is also less important than the climate change averaged over several years. Figure 3 shows surface temperature anomalies of the past 10 years relative to both a 1880-1920 base period and the usual 1951-1980 base period. The figure also shows these results both with and without the flaw in our temperature analysis.

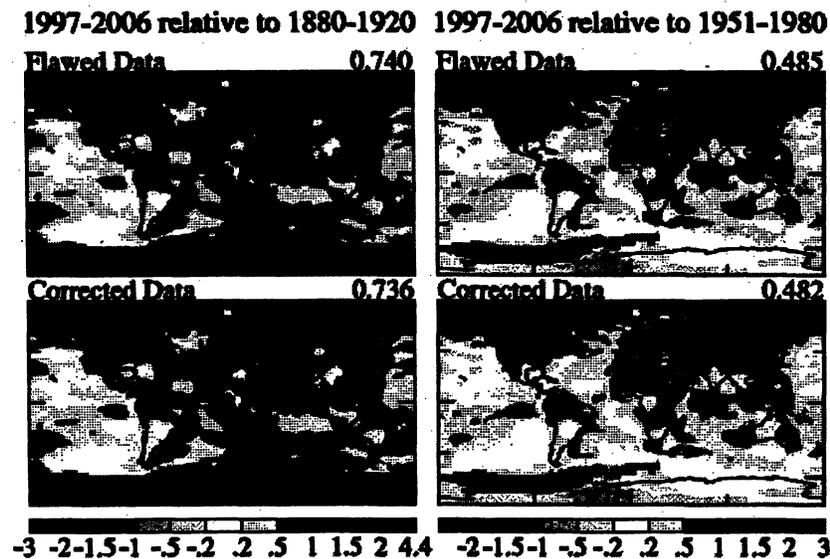

Figure 3. Surface temperature anomalies in the past 10 years (1997-2006) relative to two alternative base periods, 1880-1920 on the left and 1951-1980 on the right. The top row versus the bottom row shows the effect of the data flaw.

Over the past 30 years temperature isotherms have been moving poleward in the Northern Hemisphere land areas at a rate of about 50 km per decade. If the movements were fluctuations their impacts would be limited, but continual changes of the same sense have a cumulative effect, and under business-as-usual growth of greenhouse gas emissions the rate of movement of isotherms could double this century (see "Dangerous" paper and others on our web site).

Implications of this rapid and growing global climate change are discussed in "The 800 Pound Gorilla: The Threat and Taming of Global Climate Change", adapted from "The Threat to the Planet" in the 13 July 2006 New York Review of Books with assistance of Walter Simpson. The "Gorilla" version includes sidebars on Likely Consequences of Global Climate Change and Three Policies Needed to Defuse the Global Warming Time Bomb.

Usufruct. The deceit and guile behind the attempts to discredit evidence of climate change reveal matters of great importance. This deceit and guile has a clear purpose: it is to confuse the public about knowledge of global climate change, thus delaying effective action to mitigate climate change. The great danger is that delay will cause tipping points to be passed, such that large climate impacts become inevitable, including the loss of all Arctic sea ice, destabilization of the West Antarctic ice sheet with disastrous sea level rise later this century, and extermination of a large fraction of animal and plant species (see especially "Trace Gases" and "Dangerous" papers).

Make no doubt about it, however, if tipping points are passed, if we, in effect, destroy creation, passing on to our children, grandchildren and the unborn a situation that is out of their control, the contrarians who work to deny and confuse will not be the principal culprits. The contrarians will be remembered as no more than court jesters. There is no point to joust with court jesters. They will always be present. They will continue to entertain even if the Titanic begins to take on water. Their role and consequence is only as a diversion from what is important.

The real deal is this: the royalty controlling the court, the ones with the power, the ones with the ability to make a difference, the ability to have changed course earlier, the ones who will live in infamy, are the captains of industry, CEOs of EXXON/Mobil, automobile manufacturers, utilities, all of the leaders who have placed short-term profit above the fate of the planet and the well-being of our children. The court jesters are their jesters, occasionally paid for their services, but more substantively supported by the captains' disinformation campaigns.

Court jesters serve as a distraction, a distraction from usufruct. Usufruct is the matter that the captains wish to deny, the matter that they do not want their children to know about. They realize that if there is no gorilla, than usufruct is not an important issue for them. So they hire jesters to deny the existence of the gorilla. There is no danger of melting the Arctic, of destabilizing West Antarctica, of... regional extremes, species. Whew! So the captains can continue their business without the necessity of facing reality, of figuring out how to maintain profits without destroying their legacy in their children's eyes.

Usufruct is as American as the Declaration of Independence, with "xxxx" in its Preamble. Usufruct is discussed explicitly in a famous letter from Jefferson to Madison...

Native Americans, chief Oren Lyons.

It is time for the captains of industry to rethink their positions. I do not mean, time to polish their image with marginal investments, 'green' advertisements, and other public relations gimics. I mean, time to consider how they will function as we move toward a cleaner world 'beyond petroleum', to invest in approaches that will help take us from here to there, and to

begin to move smartly in that direction. There is still time to avert the most dramatic climate effects, if we promptly begin to address both CO₂ and non-CO₂ climate forcings. Just barely.

In

I am always a bit puzzled by the views that seem to come from conservative extremes, a bit disconcerting as I come from a moderately conservative state and consider myself a moderate conservative in most ways – puzzling because it seems to me that conservatives should be the first ones standing up for preserving Creation and for the rights of the young and the unborn. After all, that is the basic intergenerational issue in global warming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

Bush senior: “American way of life is not negotiable.”

The unborn

Do not wish to focus on the

Is it possible that moderate conservatives have been too quick to support the captains of industry? If we allow them to continue on a path of denial, to focus on their short-term profits, to deny the rights of our children, grandchildren and the unborn, if the planet passes the tipping points that assure the consequences for

Will we not share in the infamy, the infamy of the captains of industry?

Do not wish to end on a negative note. As discussed in OKCII

The Real Deal: Usufruct & the Gorilla

Fox, Washington Times, and their like have gone bananas over a flaw discovered in the computer program that produces global temperatures at GISS each month. They have even managed to get Congress and NASA Headquarters involved. Now we know what mom meant when she said "don't make a federal case out of it." Hey, what is really going on here?

The said computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001)

http://pubs.giss.nasa.gov/docs/2001/2001_Hansen_etal.pdf The flaw affected temperatures only in the United States (by about 0.15°C) and only in 2000 and later. We corrected the flaw in the program, thanked the fellow who pointed it out, and thought that was the end of it.

[The correction: As explained in the e-mail sent last week,

http://www.columbia.edu/~jeh1/distro_LightUpstairs_70810.pdf

one improvement made in our 2001 analysis was to use USHCN (U.S. Historical Climatology Network) station records in the U.S. as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day of temperature measurements, etc. Our computer program presumed that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program instead picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatsoever on the global warming issue? Certainly not, as discussed below.

What we have here is a case of dogged contrarians who present results in ways intended to deceive the public into believing that the changes have greater significance than reality. They aim to make a mountain out of a mole hill. I believe that these people are not stupid, instead they

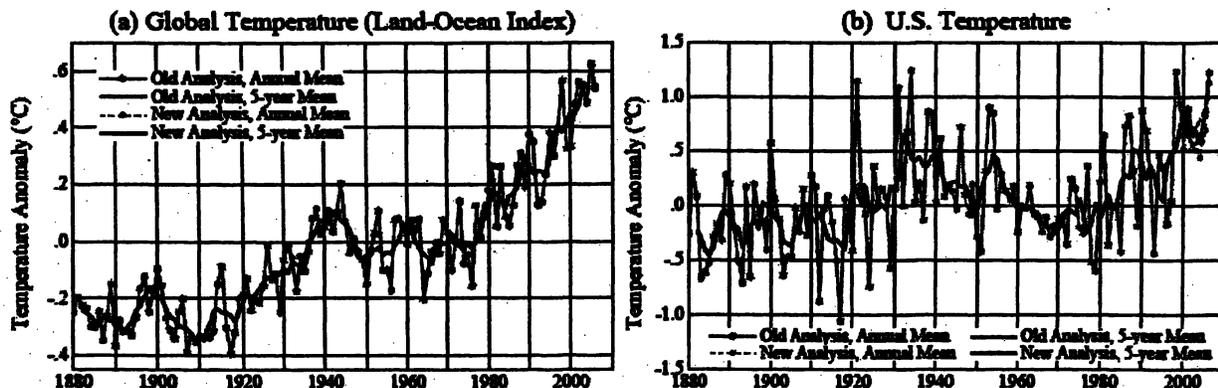

Figure 1. Global (a) and U.S. (b) before and after correction of flaw in computer program.

seek to create a brouhaha and muddy the waters in the climate change story. They seem to know exactly what they are doing and believe they can get away with it, because the public does not have the time, inclination, and training to discern what is a significant change with regard to the global warming issue.

The proclamations of the contrarians are a deceit, but their story raises a more important matter, usufruct. It is the most important issue in the entire global warming story, in my opinion. The players in the present U.S. temperature story, we scientists included, are just bit players. The characters in the main drama are big fish, really big fish. But before we get to that matter, I need to expose how the deceit works.

Instead of showing the impact of the flaw in our analysis program via a graph such as Figure 1, as a scientist would do (and as would immediately reveal how significant the flaw was), they instead discuss ranking of temperature in different years, including many false statements. We have thus been besieged by journalists saying "they say that correcting your error caused the warmest year to become 1934 rather than a recent year, is that right!?"

Hardly. First of all, many journalists had the impression that they were talking about global temperature. As you can see from Figure 1a, global warming is unaffected by the flaw. This realization should be enough to make most journalists lose interest, as global warming refers to global temperature.

But what if you are a chauvinist and only care about temperature in the United States? Did correcting the flaw in the program change the time of calculated maximum temperature to 1934? No. If you look at our 2001 paper, and get out your micrometer, you will see that we found 1934 to be the warmest year in the United States, by a hair, of the order of 0.01°C warmer than 1998, the same as the result that we find now. Of course the difference in the 1934 and 1998 temperatures is not significant, and we made clear in our paper that such years have to be declared as being practically a dead-heat.

Indeed, when we receive new data each month, which often adds in new stations, or modifies the results at a small number of stations, the results for a given year can fluctuate as much as a few hundredths of a degree. Also the GISS ranking of years is commonly different than that obtained from the NOAA or British analyses. This is expected, as there are significant differences in the methods. For example, the urban warming that we estimate (and remove) is larger than that used by the other groups (as discussed in 2001 Hansen et al. reference above).

Let's look (Figure 2) at the temperature anomalies in the four years that yield the warmest U.S. in our analysis. The U.S. mean temperature anomalies that we obtain range from 1.25°C in 1934 to 1.13°C in 2006. Thus the total range among these four years is just over a tenth of a degree. The uncertainty in the U.S. temperature is at least that large (see our published papers), so we can only say that these four years were comparably warm and the warmest year was probably either 1934 or 1998.

Note, however, that the 1998 and 2006 temperature anomaly maps differ fundamentally from the 1934 and 1921 temperature maps. In 1998 and 2006 the world as a whole has become warmer, 1998 being aided by a very strong El Nino, but 2006 by only a very weak El Nino. In 1921 and 1934 the United States happened to be a relatively hot spot compared to the world as a whole. The next time that the U.S. temperature happens to be unusually high relative to the globe, it may be quite a barn burner.

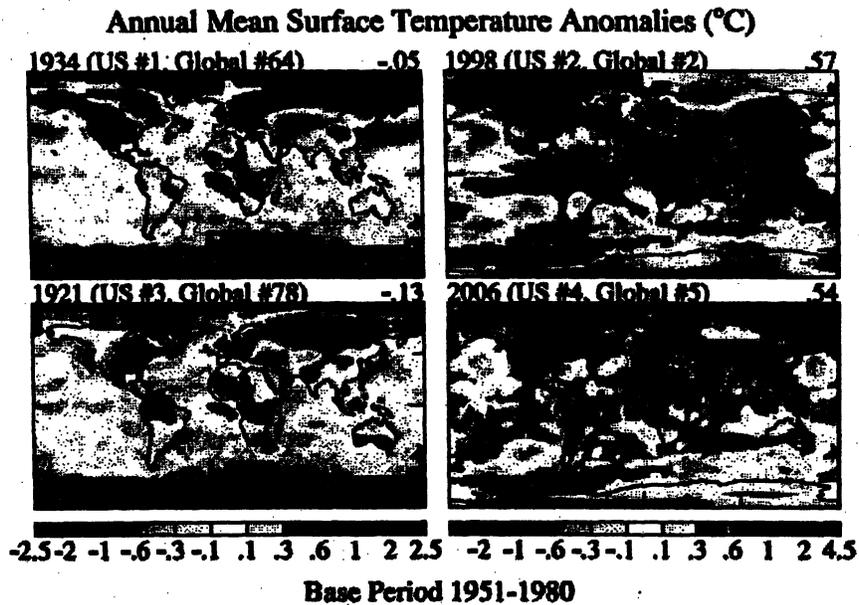

Figure 2. Temperature anomalies, relative to 1951-1980 base period, in the four years that are the warmest in the contiguous U.S. in the GISS analysis.

Although the media is always very interested in the ranking of individual years, the precise ranking is not only difficult to define accurately, it is also less important than the climate change averaged over several years. Figure 3 shows surface temperature anomalies of the past 10 years relative to both a 1880-1920 base period and the usual 1951-1980 base period. The figure also shows these results both with and without the flaw in our temperature analysis.

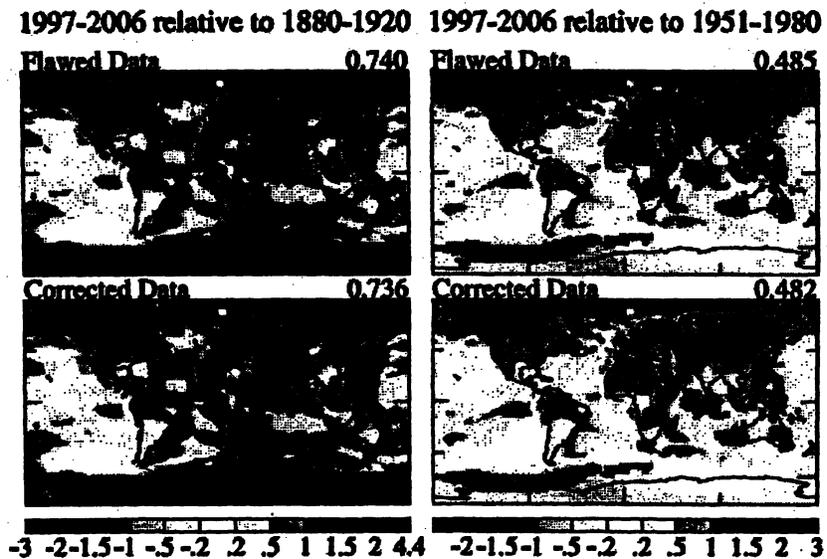

Figure 3. Surface temperature anomalies in the past 10 years (1997-2006) relative to two alternative base periods, 1880-1920 on the left and 1951-1980 on the right. The top row versus the bottom row shows the effect of the data flaw.

Over the past 30 years temperature isotherms have been moving poleward in the Northern Hemisphere land areas at a rate of about 50 km per decade. If the movements were fluctuations, their impacts would be limited. However, continual change of the same sense has a cumulative effect on the ability of species to survive in the presence of other stresses. Moreover, under business-as-usual growth of greenhouse gas emissions the rate of movement of isotherms could double this century, as discussed in several papers available on our web site, including "Dangerous" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_1.pdf "Trace Gases" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_2.pdf

Implications of this rapid and growing global climate change are discussed in "The 800 Pound Gorilla: The Threat and Taming of Global Climate Change,"

"Gorilla" <http://www.giss.nasa.gov/~jhansen/preprints/>

"Gorilla" is adapted from "The Threat to the Planet" (13 July 2006 New York Rev. Books) with assistance of Walter Simpson. "Gorilla" includes sidebars on 'Likely Consequences of Global Climate Change' and 'Three Policies Needed to Defuse the Global Warming Time Bomb'.

Usufruct. The deceit behind the attempts to discredit evidence of climate change reveals matters of importance. This deceit has a clear purpose: to confuse the public about the status of knowledge of global climate change, thus delaying effective action to mitigate climate change. The danger is that delay will cause tipping points to be passed, such that large climate impacts become inevitable, including the loss of all Arctic sea ice, destabilization of the West Antarctic ice sheet with disastrous sea level rise later this century, and extermination of a large fraction of animal and plant species (see "Dangerous", "Trace Gases", and "Gorilla" papers).

Make no doubt, however, if tipping points are passed, if we, in effect, destroy Creation, passing on to our children, grandchildren, and the unborn a situation out of their control, the contrarians who work to deny and confuse will not be the principal culprits. The contrarians will be remembered as court jesters. There is no point to joust with court jesters. They will always be present. They will continue to entertain even if the Titanic begins to take on water. Their role and consequence is only as a diversion from what is important.

The real deal is this: the 'royalty' controlling the court, the ones with the power, the ones with the ability to make a difference, with the ability to change our course, the ones who will live in infamy if we pass the tipping points, are the captains of industry, CEOs in fossil fuel companies such as EXXON/Mobil, automobile manufacturers, utilities, all of the leaders who have placed short-term profit above the fate of the planet and the well-being of our children. The court jesters are their jesters, occasionally paid for services, and more substantively supported by the captains' disinformation campaigns.

Court jesters serve as a distraction, a distraction from usufruct. Usufruct is the matter that the captains wish to deny, the matter that they do not want their children to know about. They realize that if there is no 'gorilla', then usufruct is not an important issue for them. So, with the help of jesters, they deny the existence of the gorilla. There is no danger of melting the Arctic, of destabilizing the West Antarctic ice sheet, of increasing hydrologic extremes, more droughts and stronger forest fires on one hand and heavier downpours and floods on the other, threats to the fresh water supplies of huge numbers of people in different parts of the globe. "Whew! It is lucky that, as our jesters show, these are just imaginary concerns. We captains of industry can continue with business-as-usual, we do not need to face the tough problem of how to maintain profits without destroying our legacy in our children's eyes."

Usufruct is as American as the Declaration of Independence, implicit in the Preamble "...to ourselves and our Posterity...". It is explicitly discussed in a famous letter of 6 September

1789 from Thomas Jefferson to James Madison, discussing the proposed Bill of Rights to be added to the Constitution: "The question whether one generation of men has a right to bind another. . . is a question of such consequences as not only to merit decision, but place also among the fundamental principles of every government. . . . I set out on this ground, which I suppose to be self-evident, 'that the Earth belongs in usufruct to the living' . . ."

Jefferson's philosophy regarding generational relations was based on this "self-evident" principle. That we have an obligation to preserve Creation for today's and future generations is a widely held belief. Native American Oren Lyons, a Faithkeeper in the Onondaga Nation, discusses the belief of Native Americans in their obligations to the "seventh generation". It is also a biblical paradigm that the Earth, Creation, is an intergenerational commons, the fruits and benefits of which should be accessible to every member of every generation.

Is the principle that the Earth belongs to us only in usufruct indeed self-evident and accepted by the public? In "Gorilla" I note the observation of Larry King that "nobody cares about 50 years from now." We can't take both positions. We need to make up our mind. Do we care?

I am puzzled by views expressed by some conservatives, views usually expressed in vehement unpleasant ways in e-mails that I have been bombarded by in the past several days. It is a bit disconcerting as I come from a moderately conservative state, and I consider myself a moderate conservative in most ways. It is puzzling, because it seems to me that conservatives should be the first ones standing up for preserving Creation, and for the rights of the young and the unborn. That is the basic intergenerational issue in global warming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

Is it possible that conservatives have been too quick to support the captains of industry? If we allow industry to continue on a path of denial, to focus on their short-term profits, to deny the rights of our children, grandchildren and the unborn, if the planet passes climate tipping points, will we not share in the infamy, the infamy of the captains of industry?

It seems to me that the present situation, with only minimalist actions to mitigate global climate change, reflects, at least in part, the "success" of the disinformation campaign that the captains of industry have at least tolerated, and, in some cases, encouraged and supported. Of course Nature will, eventually, reveal the truth, but there is potentially great harm in the disinformation, because it increases the likelihood that we will pass climate tipping points.

The captains of industry are smarter than their jesters. They cannot pretend that they are unaware of climate change dangers and consequences for future generations. It is time for the captains of industry to rethink their positions. I do not mean, time to polish their image with marginal investments, 'green' advertisements, and other public relations gimmicks. I mean, time to consider how they will function as we move toward a cleaner world 'beyond petroleum', to invest in approaches that will help take us from here to there, and to begin to move smartly in that direction. There is still time to avert the most dramatic climate effects, if we promptly begin to address both CO₂ and non-CO₂ climate forcings. But just barely.

I am indebted to Jim Wine for schooling me in 'usufruct'.

Criticisms, as always, are welcome.

"Gorilla" <http://www.giss.nasa.gov/~jhansen/preprints/>

"Gorilla" is adapted from "The Threat to the Planet" (13 July 2006 New York Rev. Books) with assistance of Walter Simpson. "Gorilla" includes sidebars on 'Likely Consequences of Global Climate Change' and 'Three Policies Needed to Defuse the Global Warming Time Bomb'.

Usufruct. The deceit behind the attempts to discredit evidence of climate change reveals matters of importance. This deceit has a clear purpose: to confuse the public about the status of knowledge of global climate change, thus delaying effective action to mitigate climate change. The danger is that delay will cause tipping points to be passed, such that large climate impacts become inevitable, including the loss of all Arctic sea ice, destabilization of the West Antarctic ice sheet with disastrous sea level rise later this century, and extermination of a large fraction of animal and plant species (see "Dangerous", "Trace Gases", and "Gorilla" papers).

Make no doubt, however, if tipping points are passed, if we, in effect, destroy Creation, passing on to our children, grandchildren, and the unborn a situation out of their control, the contrarians who work to deny and confuse will not be the principal culprits. The contrarians will be remembered as court jesters. There is no point to joust with court jesters. They will always be present. They will continue to entertain even if the Titanic begins to take on water. Their role and consequence is only as a diversion from what is important.

The real deal is this: the 'royalty' controlling the court, the ones with the power, the ones with the ability to make a difference, with the ability to change our course, the ones who will live in infamy if we pass the tipping points, are the captains of industry, CEOs in fossil fuel companies such as EXXON/Mobil, automobile manufacturers, utilities, all of the leaders who have placed short-term profit above the fate of the planet and the well-being of our children. The court jesters are their jesters, occasionally paid for services, and more substantively supported by the captains' disinformation campaigns.

Court jesters serve as a distraction, a distraction from usufruct. Usufruct is the matter that the captains wish to deny, the matter that they do not want their children to know about. They realize that if there is no 'gorilla', then usufruct is not an important issue for them. So, with the help of jesters, they deny the existence of the gorilla. There is no danger of melting the Arctic, of destabilizing the West Antarctic ice sheet, of increasing hydrologic extremes, more droughts and stronger forest fires on one hand and heavier downpours and floods on the other, threats to the fresh water supplies of huge numbers of people in different parts of the globe. "Whew! It is lucky that, as our jesters show, these are just imaginary concerns. We captains of industry can continue with business-as-usual, we do not need to face the tough problem of how to maintain profits without destroying our legacy in our children's eyes."

Usufruct is as American as the Declaration of Independence, implicit in the Preamble "...to ourselves and our Posterity...". It is explicitly discussed in a famous letter of 6 September

1789 from Thomas Jefferson to James Madison, discussing the proposed Bill of Rights to be added to the Constitution: "The question whether one generation of men has a right to bind another. . . is a question of such consequences as not only to merit decision, but place also among the fundamental principles of every government. . . . I set out on this ground, which I suppose to be self-evident, 'that the Earth belongs in usufruct to the living' . . ."

Jefferson's philosophy regarding generational relations was based on this "self-evident" principle. That we have an obligation to preserve Creation for today's and future generations is a widely held belief. Native American Oren Lyons, a Faithkeeper in the Onondaga Nation, discusses the belief of Native Americans in their obligations to the "seventh generation". It is also a biblical paradigm that the Earth, Creation, is an intergenerational commons, the fruits and benefits of which should be accessible to every member of every generation.

Is the principle that the Earth belongs to us only in usufruct indeed self-evident and accepted by the public? In "Gorilla" I note the observation of Larry King that "nobody cares about 50 years from now." We can't take both positions. We need to make up our mind. Do we care?

I am puzzled by views expressed by some conservatives, views usually expressed in vehement unpleasant ways in e-mails that I have been bombarded by in the past several days. It is a bit disconcerting as I come from a moderately conservative state, and I consider myself a moderate conservative in most ways. It is puzzling, because it seems to me that conservatives should be the first ones standing up for preserving Creation, and for the rights of the young and the unborn. That is the basic intergenerational issue in global warming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

Is it possible that conservatives have been too quick to support the captains of industry? If we allow industry to continue on a path of denial, to focus on their short-term profits, to deny the rights of our children, grandchildren and the unborn, if the planet passes climate tipping points, will we not share in the infamy, the infamy of the captains of industry?

It seems to me that the present situation, with only minimalist actions to mitigate global climate change, reflects, at least in part, the "success" of the disinformation campaign that the captains of industry have at least tolerated, and, in some cases, encouraged and supported. Of course Nature will, eventually, reveal the truth, but there is potentially great harm in the disinformation, because it increases the likelihood that we will pass climate tipping points.

The captains of industry are smarter than their jesters. They cannot pretend that they are unaware of climate change dangers and consequences for future generations. It is time for the captains of industry to rethink their positions. I do not mean, time to polish their image with marginal investments, 'green' advertisements, and other public relations gimmicks. I mean, time to consider how they will function as we move toward a cleaner world 'beyond petroleum', to invest in approaches that will help take us from here to there, and to begin to move smartly in that direction. There is still time to avert the most dramatic climate effects, if we promptly begin to address both CO₂ and non-CO₂ climate forcings. But just barely.

I am indebted to Jim Wine for schooling me in 'usufruct'.

Criticisms, as always, are welcome.

On 8/16/07, Zoe Cormier <@gmail.com> wrote:
 Hello Dr Hansen,

I am writing a piece on your paper in the Phil. Trans. R. Soc. A (386) on Climate change and trace gases for The Globe and Mail, Canada's largest daily paper.

I was hoping you might have a few minutes to speak with me tomorrow (Friday the 17th), or Monday the 18th.

I know that you are indeed very busy, but if you have a few minutes to discuss with me:

- why you think the IPCC may have neglected to consider those factors you included in your analysis

By its nature, science is cautious – science thrives on skepticism – so in any case it would be hard to get agreement on a topic such as ice sheet stability. But it is much harder for IPCC, because the group is necessarily composed of representatives from many countries, some of which have a natural bias in the matter.

So you cannot blame IPCC for focusing on thermal expansion and alpine glaciers, upon which it is easier to get some agreement. However, I believe that they should have said in very big red letters that they could not address ice sheet disintegration because not enough is known to give an accurate prediction for a process that is surely very non-linear. And they might have said more about the evidence from paleoclimate for ice sheets changing rapidly in the past. There is also the important evidence for what is happening on the ice sheets now, but some of that information is very recent, and because of the cumbersome IPCC review process they exclude recent information. So they are very handicapped. I do not envy them.

- the reception of your estimates by policy-makers and the IPCC

Policy-makers, at least many of them, are very glad to have input in addition to IPCC, because they recognize the handicaps that IPCC works under.

Some of the IPCC scientists agree with what I have said and written, but there are also a few old soreheads who are upset. Too bad, but it is too important a matter to worry about anyone's feelings.

and

- what overall message would you like people to get: how bad could things get and what should we be doing right now

If we follow 'business-as-usual' growth of greenhouse gas emissions, I think that we will lock in a guaranteed sea level rise of several meters, which, frankly, means that all hell is going to break loose. With so many people living near sea level it will be hard to deal with so the environmental refugees.

What we should be doing now is taking the steps to get us off the business-as-usual track. As I have written and discussed in congressional testimony, the first step should be a moratorium on new coal-fired power-plants until technology is available to capture and store the CO2. Phase-out of coal except at power plants that capture the CO2 and a gradually rising price on CO2 emissions are the main things that are needed to solve the problem.

If you can spare five minutes I would be very grateful to speak with you - but I would be happy to speak with one of your co-authors if you are not available.

Thanks and Best
 Zoe Cormier

What is the matter with the way that we do it? Among other things, we have a more realistic urban adjustment. Changing has various drawbacks. Jim

On 8/17/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Jim,

Gavin suggested some time ago that we should do the analysis with the current USHCN.

I downloaded the "FILIN" USHCN data; the filled-in numbers are marked. So I can use or ignore them. I have to write a program anyway to reformat this file to the format used by GHCN. This includes the easy conversion from F to C, but they also use a different set of ID-numbers to characterize the station. So first, I'll have to construct and check a conversion table to identify the stations properly.

Thank you for this. I will observe this condition.

I realize that you have provided some documentation of what you did. In econometrics, it is a condition of publication in journals that authors archive their code and data so that their results can be routinely replicated. I realize that no such standards apply to climate science. However, equally, there is no prohibition on individual climate scientists voluntarily adopting these best practice standards. In that

spirit, I would appreciate it if I could inspect the code used to process the GHCN data. Thanks, Steve McIntyre

After a short meeting with Dr. Hansen, we were advised to let you download whatever you want as long as generally accepted protocols are observed. Please try to do so at a time that does not impact other users, i.e. late nights, weekends.

What we did with the GHCN data is carefully documented in the publications listed on our website. We are not creating an alternate version of the GHCN data, we are mainly combining their data in various steps to create our anomaly maps.

Sincerely,

Reto A. Ruedy

CC: "Gavin Schmidt" <gschmidt@giss.nasa.gov>, "Reto Ruedy" <cdrar@giss.nasa.gov>, "Makiko Sato" <makis@giss.nasa.gov>

Technical arguments with a jackass or a jester, which most observers not wanting to understand the details, can appear to lower one to a comparable level. Better not argue with him about whether we fix data; we do an urban adjustment, for example. Jim

On 8/17/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

TOBS does not have the station history adjustment (SHAP) - FILIN has it and is the last stage before their urban adjustment. I can run with or without the filled-in data (filling in added .05C/century to the US mean trend in our analysis).

Once the new USHCN data are reformatted, it's just a question of what to do with years 2006 and 2007. Otherwise it's simply switching an input file.

I still think, Steve (in the Town Hall interview below and when he talks to anybody but us) mixes us up with Tom Karl's group - they "fix" station data, we don't. If we get this misunderstanding out in the open, it might die down as well.

"Don't tell Al Gore, but global warming is taking a holiday in Sacramento this week."

That news came in "Summer chill is one for the ages," a front-page, above-the-fold story in the August 7 *Sacramento Bee*. California's capital, normally a furnace in summer, was experiencing the lowest "high" temperatures since they began keeping records in 1877, a full 130 years ago. Such generous coverage did not extend to other cool news, including NASA's revision of the top-ten hottest years.

The hottest year on record is no longer 1998 but 1934, and the

warmest 10 years include 1921, 1931, 1934, and 1938, all before World War II. Stephen McIntyre, a Canadian, noticed an error in the NASA calculations and notified the agency, which quietly made the changes. The media were slow to respond and the *Washington Post* story of August 15 was not about the temperature change in itself, but focused on charges by conservative commentators such as Rush Limbaugh that man-made global warming was occurring within NASA.

NASA scientist James Hansen, the prime mover of global warming prophecy, downplayed the changes. The past six years, he told reporters, were only 0.15 degrees centigrade cooler than previous claims. Hansen charged that critics were trying to muddy the debate and that the slight shift changed nothing about the long-term prospects for warming, which he views as a crisis situation. The .15-degree change is more significant when one considers that the level of global warming actually detected ranges between one and two degrees Fahrenheit or .07 and .08 degrees Celsius. Hansen did not get into that, but earlier this year he did squabble with someone else over global warming – his own boss.

"I have no doubt that a trend of global warming exists. I am not sure that it is fair to say that it is a problem we must wrestle with. To assume that it is a problem is to assume that the state of the Earth's climate today is the optimal climate, the best climate that we could have or ever have had, and that we need to take steps to make sure that it doesn't change."

The speaker was NASA administrator Michael Griffin, on National Public Radio's May 31 "Morning Edition." Griffin's statement so jarred NPR staff, unaccustomed to any doubts on this issue, that they turned immediately to James Hansen.

"I almost fell off my chair," he told NPR's Madeleine Brand. "It's

remarkably uninformed. You know, civilization developed with the current climate. And we've got an infrastructure along coastlines that assumes that our climate is going to stay roughly what it is now. But if we are going to simply allow human emissions to greatly change climate, I think that's extremely arrogant of our species. It will be devastating to many other species on the planet, not to mention many of our own species."

On the same program, Mr. Hansen said, "I think it's very timely to get together and start to do something where time is really running out. . . We are at a tipping point. If we don't begin to make some changes in our emissions – reducing greenhouse gas emissions – we're going to get some really large climate changes." That is also the view of Al Gore, also in the news this summer when police arrested his son, Al Gore III, on suspicion of drug possession, and for driving a Toyota Prius 100 mph on the San Diego Freeway, 30 mph above the legal limit.

A few days later, on July 7, the former vice-president staged the massive multi-venue Live Earth concert to combat climate change, featuring such atmospheric scientists as Bon Jovi and Madonna. Two days later, on July 9, it snowed in Buenos Aires, Argentina, for the first time since 1918, nearly 90 years. That story was not widely covered in America but in Britain the *Guardian* observed, "The snow followed a bitter cold snap in late May that saw subfreezing temperatures, the coldest in 40 years in Buenos Aires. That cold wave contributed to an energy crisis and 23 deaths from exposure."

On August 4, a month after Al Gore III was arrested, the temperature in Sacramento was 104. In the next 24 hours, the temperature dropped a full 28 degrees to 74, the lowest "high" temperature for an August 5 since 1877, only a few years after Mark Twain was writing for the *Sacramento Union*. The next day, August 6, 2007, the mercury plunged still lower, to 74 F, another record and the lowest

"high" temperature for that day since 1906, 101 years ago, when the reading was 77.

Coverage of the "chill for the ages" did not include statements from Al Gore or James Hansen. Proponents of warming tend to remain silent when weather conditions fail to conform with doomsday prophecy. The summer developments, particularly the temperature shift at NASA, confirm that this creed should refrain from any claims of inerrancy.

The coverage suggests that mainstream media remain worshipful of global warming orthodoxy, and still believe that NASA knows best. They could take a lesson from Mark Twain, who warned about "such wholesale returns of conjecture out of such a trifling investment of fact." The actual low temperatures, a matter of fact, not conjecture, suggest that to doubt global warming is both reasonable and cool.

In every child's life there comes a time when childhood fantasies are shattered and he or she is forced to accept reality - there is no Santa Claus or tooth fairy; parents don't always mean it when they promise to stay married until parted by death.

Grown-up scientists, theologians, historians, archaeologists and others who pursue facts and objective truths are rooted in reality and constantly adjusting their conclusions, theories and hypotheses when new information comes to light. Those who ignore facts and cling to outdated information, or outright falsehoods, can quickly embrace fanaticism.

So it is with "global warming," the secular religion of our day that even has a good number of adherents among people of faith. Having decided to focus less on the eternal and whether anyone dwells there, global warming fundamentalists are pushing planet worship on us in a manner that would make a jihadist proud.

There are at least two characteristics all fundamentalists share. One is the exclusion and sometimes suppression of any and all information that challenges or contradicts the belief one wishes to impose on all. The other is the use of the state in pursuit of their objectives, overriding the majority's will.

With global warming, some members of the scientific community - not all of whom are climatologists, who disagree among themselves - have circled the wagons, denying access and labeling illegitimate any scientist who disagrees with the "doctrines" of a recently warming planet. The big media have been complicit in this censorship or ridicule of alternative views, mostly refusing to interview anyone who does not push the global warming faith. CBS News this week broadcast a

A protester sets up camp at the camp for Climate Action on the site of the proposed expansion for Heathrow Airport at Sipson near London August 14, 2007. Hundreds of climate demonstrators set up a tent camp next to London's Heathrow airport on Monday and threatened "direct action" at the world's busiest air hub to protest against global warming. REUTERS/Luke MacGregor (BRITAIN)

four-part series on "climate change." Newsweek magazine recently slammed global warming "deniers." That brought a counterattack in the Aug. 20 issue from Newsweek contributor Robert Samuelson, who termed the article "highly contrived" and "fundamentally misleading." In 1975, Newsweek was just as convinced - using "scientific evidence" - that a new Ice Age was upon us.

Many global warming fanatics have pointed to NASA as proof that their concerns about a warming planet are justified. They have repeatedly cited the Goddard Institute for Space Studies (GISS), whose director, James Hansen, has asserted that nine of the 10 warmest years in history have occurred since 1995, with 1998 the warmest. When NASA was confronted with evidence provided by Climate Audit, a blog run by Stephen McIntyre devoted to auditing the statistical methods and data used in historical reconstructions of past climate data, it reversed itself. Without the fanfare used to hype the global warming fanaticism it had earlier supported, NASA now says four of the top 10 years of high temperatures are from the 1930s. Several previously selected "warm" years - 2000, 2002, 2003 and 2004 - fell behind 1900.

GISS now says its previous claim that 1998 was the warmest year in American history is no longer valid. The warmest year was 1934.

Has any of this new information changed the minds of the global warming fundamentalists? Nope. Neither has much of it seen the light of day in the mainstream media, which continue to carry stories where seldom is heard an alternative word and the skies are polluted all day.

The New York Times ran a story in its Sunday Business section last week that said it would cost a lot of money to fight global warming. The implication being that this money should come from government (and taxpayers), along with more government regulations and control over our lives by the very people who seem to have difficulty winning wars and controlling spending.

The Earth has warmed and cooled over many centuries. One can get a sense of who is telling the truth about global warming by the company the concept keeps. Most of the disciples of global warming are liberal Democrats who never have enough of our money and believe there are never enough regulations concerning the way we lead our lives. That ought to be enough to give everyone pause, along with emerging evidence that the global warming jihadists may be more full of hot air than the climate they claim is about to burn us up.

It is no bother, but as I just noted to another member of the public, it is impossible to keep up with this disinformation that some people want to spread. Their aim seems to be to sew confusion, and they are succeeding. Cal Thomas' statements are wrong -- partly he has confused U.S. and global temperature, but the statements are not even true for the U.S. I will forward a piece that should clarify the matter.

Jim Hansen

On 8/20/07,

:@comcast.net> wrote:

Sorry to burden you with a quick question, which I hope one of you can answer. Our daily newspaper recently printed a column by Cal Thomas attempting to discredit concern about global warming by alleging that NASA was wrong in arguing that 9 out of 10 of the warmest years on record have occurred since 1995. Instead he says that thanks to McIntyre it is now clear that 4 of the 10 warmest years were in the 1930s, that 2000, 2002, 2003, 2004 actually fall behind 1900, and that the warmest year on record is 1934. I note that the GISS website does credit McIntyre with some kind of correction, but as I look at your latest graphs (perhaps I am not looking at the right ones) it does not appear to me that 1900 or the 1930s had record warm years. Since I hope to write an op-ed piece for the local paper (Naples Florida Daily News) I would like to know how much if any truth lies in what Thomas says. Thank you for any information you can provide, and again sorry to bother you.

For the sake of minimizing the number of data sets, you may as well drop the case that singles out two stations. The comparisons that I will want to use are with data as we adjust it and with no stations adjusted. Whether we mentioned two stations explicitly in the paper doesn't really matter -- we did adjust them. The two extreme cases make a shorter, cleaner story.

I believe that we have clearly stated several times that the ranking does not make much sense. Although we have discouraged it, anyone can see the results, so they can do the ranking themselves.

The uncertainty due to incomplete spatial coverage is objective, based on sampling a complete data set with realistic temporal-spatial variability with the actual station locations. Incomplete spatial coverage is probably the largest source of error. It is the reason that other groups did not find 2005 to be the warmest year, because they did not include the complete Arctic, which had a huge positive anomaly. We included it via our interpolations, and we verified from satellite measurements that the Arctic anomaly was, if anything, actually larger than we obtained with our interpolations.

Other components of the complete error bar must, indeed, involve some subjectivity, and they are a function of time, i.e., the uncertainty in comparing two near by years is much less than in comparing recent results to those many decades earlier..

Jim

On 8/23/07, Andrew Revkin <anrevk@nytimes.com> wrote:

howdy,

hoping we can chat briefly about the temperature-record revision.

much of this seems simply to reflect the importance of anyone (noaa, nasa, etc) clearly stating when uncertainties preclude designating years (particularly regionally) as a string of firm points, one of which can be deemed a 'record.'

noaa says it's working on an error-bar approach to its time series (but also said there are subjectivity issues that come in when doing so..?).

David, it should not affect the comparison of 1934 and 1998, and does not. If you look in our 2001 paper you will see that we had 1934 as the warmest year, by an imperceptible, insignificant amount, as we do now. We find that the Mc turkey seems to be making up stuff to try to get media attention. Jim (Do you have my Gorilla e+mail - not sure if you are on my email list.

On 8/23/07, David Easterling <David.Easterling@noaa.gov> wrote:

Hi Jim,

We are starting to get questions about the differences between our US temps and yours. We are trying to understand why substituting the adjusted USHCN data for the unadjusted starting in 1999 would make much of a difference, esp. 1998. The way I understand it you guys were pulling the unadjusted GHCN updates rather than the adjusted updates, correct? Other than than you are making urban adjustments based on the satellite lights, whereas ours is still using the old population regression adjustment.

One other fly in the ointment, we have a new adjustment scheme for USHCN (V2) that appears to adjust out some, if not most, of the "local" trend that includes land use change and urban warming.

Best,
Dave

We can add an uncertainty, indeed we already include a bar at several points on our temperature curve, but we note that it only includes the largest source of uncertainty in the temperature change (incomplete spatial coverage).

As far as I know we do not make such a list. We don't like such lists, because the results are not significant and are certain to differ from one group to another. It is generally the media that makes a list. We look for a new record high, but note that it is a virtual tie if the difference is small.

Just look at our published paper. It has 1934 as the warmest year, by an insignificant amount, with 1998 second. The same result that we have now. This ranking was not affected by the flaw in post 2000 data.

Of course it is good to improve the station data. Temperature is an absolute measurement, however, so errors over time are not cumulative. When there are several thousand stations it is easy to find what seem like a huge number of stations with problems.

Not sure that I understand this. It mentions 1934 and 1998 were tied for several months in our monthly updates, but later you say that 1998 was warmest (presumably by a meaningless 0.01, although I do not remember that - and why would we have cared or why would we have checked that)? In general I think that we want to avoid going into more and more detail about ranking of individual years. As far as I remember, we have always discouraged that as being somewhat nonsensical, other than the question of what is the warmest year, with uncertainty. Also I don't think that people, such as Gore, are being unreasonable when they make statements such as (about) 9 of 10 warmest years were in the past two decades, or however they say that -- but this of course refers to global temperature, which is much less noisy and more relevant to the question of human-made climate change. The contrarians are cleverly mixing up these two matters, global and U.S., thus completely confusing the public discussion, and again winning more time in their attempt to keep things confused, not without aid from their unwitting ally, the media. As I tried to make clear in 'Usufruct', that is the real battle, as we are running out of time. They will live in infamy, but they either do not understand or they don't give a damn. Jim

On 8/23/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Jim,

I don't know whether Andrew Revkin is interested in the details below:

The US temperature graph in our 1999 paper, based on GHCN data, shows 1934 0.5C warmer than 1998; 1998 was in 5th place behind 1921, 1931, 1938, 1953.

In the corresponding graph in our 2001 paper, now based on the carefully corrected USHCN data, 1934 and 1998 are in first, 1921 in third place (NOAA who provided the USHCN data had 1998 slightly ahead of 1934).

The US table we had posted during all of 2006 showed 1998 and 1934 even at 1.24C. (I got a copy from a journalist in Brazil, we don't save these data).

As far as I know, the US table on our site from Jan to Aug 2007 was the first and only one with 1998 ahead of 1934 - some US stations must have still been missing in the GHCN file we downloaded on January 8, 2007. (Each month, GHCN regenerates the whole file over a period of a few days; in previous years we had to wait til mid January for the US stations to be added in again).

Ruedy" <cdrar@giss.nasa.gov>

CC: James.E.Hansen@nasa.gov

Makiko or Reto, I presume that the numbers is referring to are from our global temperature analysis, is that right?

the exaggerated flap refers to the estimated mean temperature for the area covered by the 48 contiguous states, covering 2% of the globe. 1934 and 1998 (for the U.S.) have long been indistinguishable in our analysis, differing by an insignificant few hundredths of a degree. There was a flaw in our computer program that affected temperatures over the U.S. after 2000 (which affected global temperatures by an imperceptible amount, in the third decimal); the global temperature was of course much higher in 1998 than in 1934. We described 1934 and 1998 over the U.S. as a statistical dead-heat, but it has flipped from one to the other when additional stations are added or corrections are provided for existing stations, analogous to election results changing with recounts or addition of late ballots. Unlike an election, though the flip really doesn't matter as you should just say they are practically the same. It does give fodder to bloggers and Rush, though.

Note also, although the year to year fluctuations are large for an area the size of the contiguous states, the long-term (century scale) warming has been as large for the U.S. as for the global mean (actually a bit larger).

Jim Hansen

Alan, you have been given some misinformation -- I will forward a couple of e-mails that clarify. Jim Hansen

On 8/25/07, Alan Dyer <alandyer@telusplanet.net> wrote:

Hello Dr. Hansen,

I'm with the science centre in Calgary, Canada and am looking for some authoritative and quotable information on what GISS researchers have measured as the warmest years in the last century. The information I have from Goddard press releases such as at:

http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html

is that 2005, 1998, 2002, 2003 and 2006 are the warmest years of the last 100 years.

However, a columnist for a local newspaper in an August 24 editorial denying global warming and Arctic ice reduction quotes Goddard research as saying this:

NASA's Goddard Institute for Space Studies had to back down from its previous claim that 1998 was the U.S.'s hottest year on record. That distinction now goes to 1934.

Indeed, four of the hottest years on record are in the 1930s and polar bears survived just fine.

Before I counter with any rebuttal or letter to the editor I wanted to check what might be the source of that "fact" attributed to Goddard research and how the writer might have misconstrued some statement out of GISS. I'm looking for a quote I can include in my rebuttal and even a reference to some published paper that provides an authoritative answer to the question of "what were the warmest years."

Many thanks for your time.

Hi Jack,

Just back It seems to me that the paragraph is basically o.k., but I would like Reto and Makiko to verify that.

The "ranking" of individual years is something that we try to discourage media from pursuing, especially for an area the size of contiguous U.S. (2% of globe). There are too many years that are statistically indistinguishable.

Also, the results change as new stations are added to the record or old ones are changed/corrected. Indeed, WMO and/or NOAA add previously unreported data every month and often correct errors or make adjustments to some data from prior months. In general each month the data set that we obtain differs (slightly) in the past, as well as having the addition of another month. So it is like an election in which you continually have recounts and absentee ballots added. In the case of an election, change of order makes a difference, as you have to have a winner. But in the temperature analysis, in the case of razor thin differences, these flips have no physical significance (only an impact is when an eagle-eyed contrarian finds something that can be used as fodder for whatever ends they have).

Jim

On 8/23/07, Jack Kaye <jack.a.kaye@nasa.gov> wrote:

Jim - in attempting to close the loop on this so we can deal with the legislative action, I wanted to see if we could come up with any more quantitative information. I looked at the longer text that you had the link to ("The Real Deal: Usufruct & the Gorilla).

First, it appears that the "XX July 2007" in your message below should be 7 August 2007.

In terms of 1934 vis a vis the more recent years, the key data I see from your text that may be worth citing are:

- The four warmest US years on record were 1921, 1934, 1998, and 2006
- The mean temperature anomaly in the US was 1.25 deg C in 1934 and 1.13 deg C in 2006, which is the ~ 1/10 degree difference between the two, which is smaller than the uncertainty in the actual numbers.
- In 1934 the US was warm relative to much of the rest of the world, while in 2006 the world was much warmer.

If these points are enough, we can try to get them into a short paragraph. How about this?

The computer program used by Dr. Hansen to create the temperature record is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen in a peer-reviewed publication from 2001. The flaw affected temperatures only in the United States and only after 2000. As explained by Dr. Hansen in an e-mail sent out on August 10, one of the improvements made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the United States as adjusted by Thomas Karl of NOAA's National Climatic Data Center and his colleagues, who

used available descriptive data to correct for effects of station moves, changes in time-of-day at which measurements were made, etc. Dr. Hansen's computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and his computer program picked up the data for these same stations reported in the World Meteorological Organization's GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in the temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISS Temperature web page. Based on the current analysis, the four warmest years in the US record were 1921, 1934, 1998, and 2006. The mean temperature anomaly in the US was approximately 1/10 degree C greater in 1934 (1.25 degrees) than in 2006 (1.13 degrees); this difference is less than the uncertainty in the calculated mean. One point worth noting is that in 1934, the US was warm relative to much of the rest of the world, while in 2006, the warmth of the US was accompanied by that of much of the globe.

Would you be okay with this? If not, do you have suggestions? I don't know that we'd need much more than this!

On 8/15/07 2:27 AM, "James Hansen" <jhansen@giss.nasa.gov> wrote:

Jack, I am writing something, with figures, which I will send later today. Here are a few relevant paragraphs for now. Jim

The computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001). The flaw affected temperatures only in the United States and only after 2000.

[As explained in the e-mail sent out last week, one of the improvements made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the United States as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day at which measurements were made, etc. Our computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in the temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on XX July 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

:On 8/14/07, Jack Kaye <jack.a.kaye@nasa.gov> wrote:

Jim - thanks for sending this to me.

We have an action to respond to a Congressional question about this.

Can you provide us with a relatively straightforward answer (with some #) that we can transmit? I don't think we need anything extensive or complex, but a relatively brief (but quantitative) "just the facts" summary would help. As a backup, it may be good if we could have some # in case we get asked for more detail (e.g., list of top 20 warm years, time series of global T for last 15 years and also for 1934 +/- 5 years).

Don is on travel, but may be checking e-mail.

Time scale is, of course, asap! - Jack

On 8/14/07 2:52 AM, "James Hansen" < jhansen@giss.nasa.gov > wrote:

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S.

Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they

based on metadata available station by station for station moves, time-of-observation bias, etc.

However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected by adding the NOAA/NCDC adjustment near the end of the record to the 2001-2007 data, and it has been so corrected.

Don et al.,

I saw this on the NASA news summary today.

**Columnist Notes Changes In
NASA's Temperature Data. In
an op-ed for the Washington
Times (8/13, 87K) Mark Steyn, a**

syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, " Something rather odd happened the other day. If you go to NASA's Web site and look at the " U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com [<http://climateaudit.com/>](http://climateaudit.com/) [<http://climateaudit.com/>](http://climateaudit.com/) labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that

would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even American: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

- > Because of its peculiar location, the Yucatan takes more big hurricane hits than just about anywhere else in the western hemisphere. When Mexico was dirt-poor, as it was in 1955, hurricanes could kill hundreds. They were warned, then, too. Hurricane-hunter planes also monitored Janet. Only one of these has ever been lost, and it as Janet was making landfall.
- >
- > Similar storms, huge storms, very different results. What's happening here?
- >
- > Since then, people in the Yucatan have learned to adapt. While storms like these used to kill hundreds, even thousands, we now have the technology to forecast their tracks, at least for the critical last 24 hours, with reasonable confidence. Forecasting the intensity is a bit trickier, but everyone in the hurricane business was pretty convinced that Dean was going to bomb out sometime before it hit land. After all, it was passing over the same region in which 1988 hurricane Gilbert set the record for the lowest barometric pressure ever measured in the Atlantic Basin.
- >
- > Gilbert was the second-strongest storm ever recorded at landfall, and also hit the Yucatan. While it was responsible for 202 deaths in Mexico, almost all of these were caused by mountain floods hundreds of miles away and days away from landfall.
- >
- > Adaptation includes technology, infrastructure, and response. National Hurricane Center forecasts and data are available to everyone. But the infrastructure to respond to a forecast hurricane costs money, and poor nations don't have it. Among other things, it requires good roads for evacuation.
- >
- > Perhaps even more important, adaptation to hurricanes or other natural disasters is political. No elected official wants to be blamed for hundreds of preventable deaths, so the nations that can afford it develop evacuation plans, open shelters, and deliver people from danger.
- >
- > When Janet killed hundreds, per-capita income in Mexico was less than a tenth of what it is now, when Dean killed no one.

- >
- > So why is it that people are wringing their hands about global warming causing more severe hurricanes and deaths?
- >
- > The best computer estimate for future hurricanes was published by Tom Knutson and Robert Tuleya in the Journal of Climate in 2004. They calculated that maximum winds should increase by about 6% over the next 75 years. Even this may be an overestimate because the method used assumes carbon dioxide—the main global warming emission—is increasing in the atmosphere about twice as fast as it actually is.
- >
- > Clearly, this small increase in hurricane strength is going to be dramatically overshadowed by adaptation as the developing world continues to develop. Mexico is a case in point.
- >
- > We see other adaptations to climate change in our cities. In the United States, cities with the most frequent heat waves have the fewest heat-related deaths, and heat-related deaths are themselves dropping, as our cities warm. Remember, a city doesn't need global warming to get hot. All it needs is a skyline, and a lot of blacktop and concrete to impede the flow of air and retain heat. But in our warming cities, just as with hurricanes in the Yucatan, frequency + affluence = adaptation.
- >
- > An odd example of this is that there is only one major U.S. city in which heat related deaths are increasing, and it is the coolest one in summer: Seattle.
- >
- > Anyone concerned about climate change should take a lesson from Hurricane Dean. Even if storms like this become more frequent in the future, people will adapt and survive if they have the financial resources. How silly it seems to take those resources away in futile attempts to "stop global warming"—which no one even knows how to do—when they could save lives by allowing people to adapt to our ever-changing climate.
- >
- > The truth is that money in the hand is a lot more useful than treaties on paper when it comes to sparing yourself and your family from bad weather. So people truly worried about climate change should be cheerleading for the global trade and economic development that will continue allowing us to adapt.

> Michael Schirber

> Since the late 1960s, much of the North Atlantic Ocean has become less salty, in part due to increases in fresh water runoff induced by global warming, scientists say. Now for the first time researchers have quantified this fresh water influx, allowing them to predict the long-term effects on a "conveyor belt" of ocean currents.

> Climate changes in the Northern Hemisphere have melted glaciers and brought more rain, dumping more fresh water into the oceans, according to the analysis.

> One of the expected high-profile consequences is a rising sea that will swamp coastal communities....

> **GLOBAL WARMING MAKES NORTH ATLANTIC MORE SALTY**

- >
- > New Scientist, 23 August 2007
- > http://environment.newscientist.com/article.ns?id=dn12528&feedId=online-news_rss20

> Catherine Brahic

> The surface waters of the North Atlantic are getting saltier, suggests a new study of records spanning over 50 years. And this might actually be good news for the effects of climate change on global ocean currents in the short-term, say the study's researchers.

> This is because saltier waters in the upper levels of the North Atlantic ocean may mean that the global ocean conveyor belt – the vital piece of planetary plumbing which some scientists fear may slow down because of global warming – will remain stable.

> The global ocean conveyor belt is the crucial circulation of ocean waters around the Earth. It helps drive the Gulf Stream and keeps Europe warm. The density of waters which drives the flow of ocean currents is dependent on temperature and

salinity, so any change in saltiness may have an impact.

>
> Tim Boyer of the US National Oceanographic Data Center and colleagues compiled salinity data gathered by fisheries, navy and research ships travelling across the North Atlantic between 1955 and 2006. They found that during this time, the layer of water that makes up the top 400 metres has gradually become saltier.

>
> The seawater is probably becoming saltier due to global warming, Boyer says. "We know that upper ocean is warming in the North Atlantic, so it stands to reason that there should be more evaporation, making waters more salty," he says.

> <http://www.forbes.com/feeds/ap/2007/08/23/ap4050345.html>

>
> By ARTHUR MAX

>
> AMSTERDAM, Netherlands - The treaty that will eventually replace the Kyoto Protocol on climate change could be a potpourri of legal obligations, nonbinding commitments and aid arrangements for the developing world, but each nation should choose its own course, the U.N.'s top climate official said Thursday.

>
> At the outset of a season of climate negotiations, Yvo de Boer, executive secretary of the U.N. Framework Convention on Climate Change, said countries such as the United States are mistaken if they dismiss the Kyoto process on the grounds it is forcing them into unwanted legal commitments.

>
> "Countries themselves are in the best position to decide how they can achieve a target to which they commit," he told The Associated Press from his headquarters in Bonn, Germany. "You should not seek to impose legally binding commitments on countries."

>
> At the same time, he said, it was up to the industrialized nations to take the lead in fighting global warming, and that binding commitments give a strong signal to energy investors on where to put their money.

>
> De Boer's comments appeared aimed at minimizing differences with the United States, which opted out of binding international agreements, but which is now trying to seize the initiative in shaping the next phase of world climate policy.

>
> The U.S. position has angered the European Union, which has adopted increasingly higher targets and imposed tough regulations on its member nations beyond their Kyoto commitments.

>
> President Bush has called a conference in Washington next month of the world's 15 biggest polluters, including India, China and several other countries not bound by the 1997 Kyoto Protocol, which expires in 2012. De Boer will head the U.N. delegation.

>
> That meeting will take place three days after a broader meeting on climate change summoned by U.N. Secretary-General Ban Ki-moon on Sept. 24 in New York. Both the Washington and New York talks are geared toward a major U.N. meeting in Bali, Indonesia, in December to discuss a successor agreement to Kyoto.

>
> The Kyoto agreement requires 35 industrial nations to cut their global-warming emissions 5 percent below 1990 levels by 2012. It also devised a carbon trading market and set up a system for nations to offset part of their obligations by sponsoring emission-reduction projects in developing countries. De Boer said 700 such projects - such as financing hydroelectric or wind power projects - are in the pipeline.

>
> De Boer said an important element in the post-Kyoto climate regime will be how countries can gain credit by helping the developing world.

>
> "It makes sense to get the biggest bang for your bucks, to identify the most cost-effective emissions reduction options around the world. The atmosphere doesn't care where you reduce emissions as long as you reduce emissions," he said.

Subject: Re: new USHCN 1880-2005

From: James Hansen <jhansen@giss.nasa.gov>

Date: Mon, 27 Aug 2007 18:42:10 -0400

To: ruedy@giss.nasa.gov, Gavin Schmidt <gschmidt@giss.nasa.gov>, makis@giss.nasa.gov

This is excellent. This is consistent with the philosophy described in our 2001 paper, i.e., letting NOAA do the primary, labor-intensive task of cleaning U.S. station data. But it is appropriate for us to do our own urban correction using satellite night lights. I believe that they (NOAA) have underestimated urban warming effects, so it is better that we keep our own urban correction.

By the way, in case there is any question about why we get into this (surface temperature analysis) business at all, given NOAA's responsibilities: originally (in the 1970s) this was because there was no global analysis, the only available analysis being Murray Mitchell's, which only went down to 20N latitude. We showed that Southern Hemisphere coverage was actually useful, because of the large correlation distance of anomalies.

Funny thing is that, despite the much larger (person-wise) efforts that the other groups put into this, our analysis scheme still proved useful in 2005. The reason that we found 2005 (slightly) warmer than 1998 was that we included the full Arctic. And satellite IR data suggest that, if anything, our Arctic anomalies underestimate the actual positive anomalies there.

Jim

Gavin,

Yes it was done properly this time - also, just looking at the annual US-means, that method seems to do pretty well. Steve will find the few stations where it didn't.

I thought of taking any detailed descriptions out of the "Background" section with links to separate pages, where the processes are carefully described and which are updated, whenever a change is made, noting the date when the change occurred. That should satisfy most people.

Rounding to the nearest .1C was Phil Jones' suggestion; I realize that we have to wait a while to do so.

Subject: The 1934 flap

From: "James Hansen" <jhansen@giss.nasa.gov>

Date: Mon, 27 Aug 2007 21:03:20 -0400

To: "Makiko Sato" <makis@giss.nasa.gov>, "Reto Ruedy" <cdrar@giss.nasa.gov>, @aol.com" < @aol.com>

Yes, I should make clear what I meant. I know that if you take the linear trend the U.S. temperature change is less than the global trend. But if you compare the mean for the past 10 years to the mean for either 1880-1900 or 1880-1920, the warming is about 1.0C (1.8F) for the U.S. and 0.8C for the global mean. Ten years is enough to pretty well average out the large year-to-year fluctuations, so I think it is a fair way to look at the magnitude of the warming. In a case where you have a large change near the end of the record the linear trend is not a very good way to look at the magnitude of the change. Jim

Jim,

Fig 1: Global map

The global trend is 0.65 (and 0.64 for 1906-2006), and the US averages yellow, which means about 0.35, almost half of the globe, but why did you write as above?

Hi Lonnie,

O.K., I am trying to avoid commitments because I am so far behind on things, but it would be good to see you again. Let's make it near the end of the periods you mention, i.e., at the beginning of May.

Will try to call you now.

Jim

On 8/28/07, Lonnie Thompson <thompson.3@osu.edu> wrote:

Hi Jim: Understand you have had a busy summer. I had a few issues I would like to touch base with you on.

(1) Concerns telephone call with Ralph Cicerone concerning Steve McIntyre, data request and tactics.

(2) Would like to get you to Ohio State in 2008 to give the Bownocker Lectures. We are pretty open on times. The lectures are scheduled on Thursday but any Thursday between Feb. 21 and March 6th or between March 27 and May 8th would work. There are two lecture:

one at 4:00 PM which is more technical and a public lecture a 8:00 PM. These would be in our new School of Earth Sciences.

All expenses would be paid and there is a \$1000.00 honorarium. More important, I know how busy you are and the toll that lectures take.

I will be on a 10 day major city Einstein Lecture tour in China in October but feel sometimes it is the best way to get the message out one person at time.

Hope you can fit us in your busy schedule next spring. Appreciate very much what you do in getting the message to the public.

Please let me know if you can fit this into your schedule.

You can telephone my direct line:

Best wishes,

Lonnie

Subject: Re: USA temperatures - question from USA TODAY

From: "James Hansen" <jhansen@giss.nasa.gov>

Date: Wed, 29 Aug 2007 03:41:30 -0400

To: "Rice, Doyle" <drice@usatoday.com>, "Makiko Sato" <makis@giss.nasa.gov>

CC: James.E.Hansen@nasa.gov, "Reto Ruedy" <cdrar@giss.nasa.gov>

Doyle,

We start from NCDC raw data, but the analysis method differs, as described in our 2001 paper. As you can discern from that paper, the factor that probably makes the difference regarding our relative rankings of 1934 and 1998 is the method of correcting for urban warming effects, ours yielding a somewhat larger correction. However, the end results are in very good agreement, as you can see by looking at the temperature curves.

Makiko, would you please make available your recent figure with global and U.S. temperature curves? Doyle, you will see that these years are practically indistinguishable. There is no way for anyone to be certain which year was warmer.

Jim

On 8/28/07, Rice, Doyle <drice@usatoday.com> wrote:

Dr. Hansen

We're trying to clarify some points about the US historical temperature record.... Does NASA use a different data set from NCDC? With the recent controversy, we want to be sure we're not comparing apples to oranges as we cover this.

According to NCDC, 2006 was the second-warmest after 1998-

<http://www.ncdc.noaa.gov/oa/climate/research/ushcn/hcntmptrends.php>

<http://www.ncdc.noaa.gov/oa/climate/research/2006/ann/ann06.html>

But I see in the NASA data, with the recent correction, 1934 is the warmest, with 1998 second followed by 1921 and 2006.

Reto, thanks, good points. Jim

On 8/29/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Jim,

You could mention one other difference:

NCDC's curve is based exclusively on the 1221 closely examined and carefully corrected USHCN full data records, GISS's curve was culled from our GLOBAL analysis, i.e. from global maps produced by combining all available station records; this includes the part of the USHCN data that could be downloaded from USHCN's web site (ending currently with year 2005), but it also uses the remaining 541 US stations, and as far as the US mean is concerned, it is also impacted by the non-US stations located within 1200 km of the US border.

Well, I guess that I would say it a bit differently.

Our method of analysis has features that are different than the analyses of the other groups. In some cases the differences have a substantial impact.

For example, we extrapolate station measurements as much as 1200 km. This allows us to include results for the full Arctic. In 2005 this turned out to be important, as the Arctic had a large positive temperature anomaly. We thus found 2005 to be the warmest year in the record, while the British did not and initially NOAA also did not. Independent satellite IR measurements showed that our extrapolations of anomalies into the Arctic were conservative. I am very confident that our result was the correct one in that instance.

Also, as we show in our 2001 paper, our urban warming correction in the U.S. differs from the NOAA correction (we have a larger adjustment, which decreases recent temperatures relative to last century). I would not claim that one is superior to the other, but the different results provide one conservative measure of uncertainty. In general it has proven very useful to have more than one group do the analysis.

Also it should be noted that the different groups have cooperated in a very friendly way to try to understand different conclusions when they arise. You will see that we had co-authors from the other groups on our 2001 paper. And in general it is a bad idea to anoint any group as being THE authority. Science doesn't usually work best that way.

Jim

On 8/29/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Doyle,

Since this is a technical question and Dr. Hansen is busy this afternoon, I'll answer it:

No, your statement is NOT correct; to get the US means, NCDC's procedure of only using the best stations is more accurate. If that were our goal, we would proceed in the same way. Actually, whenever we report on US means in our publications, we recompute all US means using only USHCN data.

My recommendation to you is to continue using NCDC's data for the US means and Phil Jones' data for the global means. Our method is geared to getting the global mean and large regional means correctly enough to assess our model results.

We are basically a modeling group and were forced into rudimentary analysis of global observed data in the 70's and early 80's since nobody else was doing that job at the time. Now we happily combine NCDC's and Hadley Center's data to get what we need to evaluate our model results. For that purpose, what we do is more than accurate enough. But we have no intention to compete with either of the other two organizations in what they do best.

Sincerely,

Reto

Hi Jack,

Just back It seems to me that the paragraph is basically o.k., but I would like Reto and Makiko to verify that.

The "ranking" of individual years is something that we try to discourage media from pursuing, especially for an area the size of contiguous U.S. (2% of globe). There are too many years that are statistically indistinguishable.

Also, the results change as new stations are added to the record or old ones are changed/corrected. Indeed, WMO and/or NOAA add previously unreported data every month and often correct errors or make adjustments to some data from prior months. In general each month the data set that we obtain differs (slightly) in the past, as well as having the addition of another month. So it is like an election in which you continually have recounts and absentee ballots added. In the case of an election, change of order makes a difference, as you have to have a winner. But in the temperature analysis, in the case of razor thin differences, these flips have no physical significance (only an impact is when an eagle-eyed contrarian finds something that can be used as fodder for whatever ends they have).

Jim

On 8/23/07, Jack Kaye <jack.a.kaye@nasa.gov> wrote:

Jim - in attempting to close the loop on this so we can deal with the legislative action, I wanted to see if we could come up with any more quantitative information. I looked at the longer text that you had the link to ("The Real Deal: Usufruct & the Gorilla).

First, it appears that the "XX July 2007" in your message below should be 7 August 2007.

In terms of 1934 vis a vis the more recent years, the key data I see from your text that may be worth citing are:

- The four warmest US years on record were 1921, 1934, 1998, and 2006
- The mean temperature anomaly in the US was 1.25 deg C in 1934 and 1.13 deg C in 2006, which is the ~ 1/10 degree difference between the two, which is smaller than the uncertainty in the actual numbers.
- In 1934 the US was warm relative to much of the rest of the world, while in 2006 the world was much warmer.

If these points are enough, we can try to get them into a short paragraph. How about this?

The computer program used by Dr. Hansen to create the temperature record is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen in a peer-reviewed publication from 2001. The flaw affected temperatures only in the United States and only after 2000. As explained by Dr. Hansen in an e-mail sent out on August 10, one of the improvements made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the United States as adjusted by Thomas Karl of NOAA's National Climatic Data Center and his colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day at which measurements were made, etc. Dr. Hansen's computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and his computer program picked up the data for these same stations reported in the World Meteorological Organization's GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in the temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISS Temperature web page. Based on the current analysis, the four warmest years in the US record were 1921, 1934, 1998, and 2006. The mean temperature anomaly in the US was approximately 1/10 degree C greater in 1934 (1.25 degrees) than in 2006 (1.13 degrees); this difference is less than the uncertainty in the calculated mean. One point worth noting is that in 1934, the US was warm relative to much of the rest of the world, while in 2006, the warmth of the US was accompanied by that of much of the globe.

Would you be okay with this? If not, do you have suggestions? I don't know that we'd need much more than this!

On 8/15/07 6:18 AM, "Jack Kaye" <jack.a.kaye@nasa.gov> wrote:

Jim - thanks for sending. I'll watch for next installment. I appreciate the prompt turnaround
- Jack

On 8/15/07 2:27 AM, "James Hansen" <jhansen@giss.nasa.gov> wrote:

Jack, I am writing something, with figures, which I will send later today. Here are a few relevant paragraphs for now. Jim

The computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001). The flaw affected temperatures only in the United States and only after 2000.

[As explained in the e-mail sent out last week, one of the improvements made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the United States as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day at which measurements were made, etc. Our computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in the temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on XX July 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure

1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

:On 8/14/07, Jack Kaye <jack.a.kaye@nasa.gov> wrote:

Jim - thanks for sending this to me.

We have an action to respond to a Congressional question about this. Can you provide us with a relatively straightforward answer (with some #) that we can transmit? I don't think we need anything extensive or complex, but a relatively brief (but quantitative) "just the facts" summary would help. As a backup, it may be good if we could have some # in case we get asked for more detail (e.g., list of top 20 warm years, time series of global T for last 15 years and also for 1934 +/- 5 years).

Don is on travel, but may be checking e-mail.

Time scale is, of course, asap! - Jack

On 8/14/07 2:52 AM, "James Hansen" <jhansen@giss.nasa.gov> wrote:

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S.

Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over

several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc.

However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected by adding the NOAA/NCDC adjustment near the end of the record to the 2001-2007 data, and it has been so corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the Washington Times (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the "U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century — 2000, 2002, 2003, 2004 — plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com

<http://climateaudit.com/>

<http://climateaudit.com/>

labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings — albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Jim,

The only factual inaccuracy is the years affected by the discontinuity:
So I would change Jack's sentence that starts with:

"The flaw affected only ..."

I would replace the end "and only after 2000" by "and only for years
2000-present"

or something like that.

Reto

Jim,

The only factual inaccuracy is the years affected by the discontinuity:
So I would change Jack's sentence that starts with:

"The flaw affected only ..."

I would replace the end "and only after 2000" by "and only for years
2000-present"

or something like that.

Subject: Re: WSJ Editorial August 29

From: "James Hansen" <jhansen@giss.nasa.gov>

Date: Fri, 31 Aug 2007 16:34:27 -0500

To: "Halpern, David (HQ-DA000)" <david.halpern@nasa.gov>

CC: "Freilich, Michael H. (HQ-DK000)" <michael.h.freilich@nasa.gov>, "Jack Kaye" <jack.a.kaye@nasa.gov>

Hi David,

Thanks for being concerned about this. WSJ clearly has objectives other than straight reporting.

Two clarifications to the below seem needed:

1) There was no change in the data processing. We pride ourselves on not continually changing the processing method. The last change was in 2001, as defined in the paper published then. We just put in the new data sets as they are updated every month by WMO and NOAA. What happened was that in 2001 we decided to use NOAA-adjusted data for the U.S. (USHCN, United States Historical Climatology Network) data, because Tom Karl et al. had gone to a lot of trouble (using station-by-station "meta-data") to correct for station moves, change of the time-of-day at which the records are read by the observers, etc. Unfortunately, we did not realize that USHCN data would not be available in near-real-time, while the WMO data for the same stations (same station ID numbers) were available (but excluding the NOAA adjustments), so the analysis picked up the unadjusted WMO data (from 2000 on) and tagged it onto the NOAA records (which went through 1999).

2) This should not be blamed on "a technician". As the person who devised the analysis procedure and as first author on the papers, I am responsible for checking the results. The way you catch these problems is by looking at the data. In fact I look at graphs and maps of the temperature anomalies each month, but I didn't notice this problem. The discontinuity at some individual stations was detectable, which is how McIntyre found it, but I did not make such graphs (there are thousands of stations). Because some stations had positive discontinuities and some negative, the flaw was small in either the line graphs of mean temperature or the maps (where the temperature at any point is based on many stations) that I look at. Because the flaw amounted to about 0.15C over the U.S. and 0.003C globally, it was much smaller than natural variability, so not detectable that way.

Jim

On 8/31/07, Halpern, David (HQ-DA000) <david.halpern@nasa.gov> wrote:

Jim,

The email messages below indicate that NASA's Earth Science Division may be willing to recommend a NASA response to the WSJ editorial for its attack on NASA science.

Do you think this is a wise move? If "yes", I'm willing to prepare some preliminary text for your review before I send it to Mike Freilich. Would you please send me a sentence about the change in data processing methodology that occurred on processing data for 2000 and afterwards. Also, why was this new algorithm applied to only the U.S. data? What were the annual differences in global annual mean temperature in 2000-2006 between the values computed with the old and new methodologies?

Best regards.

Dave

(In case you want to call me, my number is

On 8/30/07 10:17 AM, "Halpern, David (HQ-DA000)" <david.halpern@nasa.gov> wrote:

Michael,

A NASA response to the WSJ editorial is a unique opportunity to inform a large scientific and non-scientific population about the scientific method and that NASA science is conducted with openness, transparency, and the highest standards of excellence.

NASA (preferably Griffin) should refute the WSJ claim that NASA science has blunders and therefore cannot be trusted. NASA should inform the WSJ, which should have an uncanny knowledge of data processing errors, including those caused by humans, in statistical analysis of dynamic time series, that an inadvertent error occurred in processing the data in 2000 and subsequent years when a technician unknowingly used a different algorithm to process the temperature data over the United States. As a good steward of the scientific method, NASA had made public the procedure it uses to analyze the data, which allowed everyone to improve the methodology, and then made the correction the day NASA was informed. NASA immediately informed the world through the Internet following the scientific culture of openness and transparency. The negligible magnitude of the error associated with data over the United States did not change the result of the global annual mean surface air temperature, leaving 1998 the second warmest year and 2005 the warmest year since the instrumental record began 125 years ago. In addition, the WSJ incorrectly stated that the NASA data do not confirm a global warming trend in this decade (e.g., see <http://lwf.ncdc.noaa.gov/img/climate/research/2005/ann/global-blended-temp-pg.gif>). NASA's response should be coordinated with GISS, the owner of the temperature data set.

I may be over reacting. The action of doing nothing probably does no harm unless each time NASA science makes an inadvertent negligible error the WSJ (and others) claim that they told everyone that NASA science contains blunders. This could become a disaster for science.

A benefit of a NASA response is building a NASA science team showing that an attack on science is an attack on all.

I recall that Griffin responded to the Abbott-Haymet-Luyten article in the Washington Post.

Conversation: Science in the News: August 29

Subject: Science in the News: August 29

WSJournal Says NASA's "Blunder" Evidence Of Global Warming Hype. The Wall Street Journal <<http://online.wsj.com/article/SB118835472067611877.html.html>> (8/29, A14, 2.06M) editorializes, "The latest twist in the global warming saga is the revision in data at NASA's Goddard Institute for Space Studies, indicating that the warmest year on record for the U.S. was not 1998, but rather 1934 (by 0.02 of a degree Celsius)." The Journal adds, "If nothing else, the snafu calls into question how much faith to put in climate change models. In the 1990s, virtually all climate models predicted warming from 2000-2010, but the new data confirm that so far there has been no warming trend in this decade for the U.S. Whoops. ... NASA's blunder only became a news story after Internet bloggers played whistleblower by circulating the new data across the Web. So far this year NASA has issued at least five press releases that could be described as alarming on the pace of climate change. But the correction of its overestimate of global warming was merely posted on the agency's Web site. James Hansen, NASA's ubiquitous climate scientist and a man who has charged that the Bush Administration is censoring him on global warming, has been unapologetic about NASA's screw up. He claims that global warming skeptics -- 'court jesters,' he calls them -- are exploiting this incident to 'confuse the public about the status of knowledge of global climate change, thus delaying effective action to mitigate climate change.' So let's get this straight: Mr. Hansen's agency makes a mistake in a way that exaggerates the extent of warming, and this is all part of a conspiracy by 'skeptics'? It's a wonder there aren't more of them."

Swift Satellite Will Resume Studies Of Gamma-Ray Bursts. New Scientist

<<http://space.newscientist.com/article/dn12552-disoriented-space-telescope-regains-bearings-but-not-vision.html>> (8/29, Shiga) reports, "NASA's Swift satellite has regained its bearings following a glitch that prevented it from taking observations," but "it will likely be several more weeks before it can resume studying cosmic explosions called gamma-ray bursts." Swift was launched in November of 2004, and is successful in that "it is able to rapidly swivel to train its instruments on the source of each fleeting burst."

Mars Rovers Set To Return To Work. Aviation Week <http://www.aviationweek.com/aw/generic/story.jsp?id=news/rovers082807.xml&headline=Mars%20Rovers%20On%20Move%20Again%20&channel=space>

(8/29, Covault) reports, "The Mars rovers Spirit and Opportunity are on the move again after surviving electrical power shortages caused by global dust storms that have swept the red planet since early July." Since "weather and power conditions continue to improve, although very slowly, for both rovers," they are "back on schedule to communicate daily."

UPI <http://www.upi.com/NewsTrack/Science/2007/08/28/mars_rovers_resume_some_functions/5217/>

(8/29) adds that "mission controllers were taking advantage of gradual clearing of dust from the sky while also taking precautions against buildup of dust settling onto the rover." It is noted that "both rovers had become immobilized when a giant dust storm on Mars cut off their solar energy supply."

NASA Scientists Predict Wetter Tropics. The (UK) Register <http://www.theregister.co.uk/2007/08/28/tropics_wetter/>

(8/29, Sherriff) reports, "NASA researchers now say they have good evidence that the tropics are getting wetter, with more rain falling over the oceans, than on land. According to a study, published in the August 1 edition of the American Meteorological Society's Journal of Climate, 2005 was the wettest year between 1979 and the present day, followed by 2004, 2003, 2002 and 1998. 'When we look at the whole planet over almost three decades, the total amount of rain falling has changed very little. But in the tropics, where nearly two-thirds of all rain falls, there has been an increase of 5 per cent,' said lead author Guojun Gu, a research scientist based at NASA's Goddard Space Flight Center. The researchers used data from satellites and ground based observation stations to create their global record. Although the record of land based rainfall goes back many years, it is only in the last 30 years that satellite monitoring has allowed researchers to track the amount of rain falling over the seas."

NOAA Study: Human Activity Biggest Factor In 2006 High Temps. AP

<http://news.yahoo.com/s/ap/20070828/ap_on_sc/greenhouse_warming;vlt=Ar_of8dp1FgHKIX.s.q710msONUE>

(8/28, Schmid) reports, "Warming caused by human activity was the biggest factor in the high temperatures recorded in

2006, according to a report by researchers at the National Oceanic and Atmospheric Administration. The analysis, released Tuesday, is being published in the September issue of Geophysical Research Letters, published by the American Geophysical Union."

Scholar Suggests Scorching Summers Will Be Common. The AP <http://www.usatoday.com/weather/climate/globalwarming/2007-08-28-montana-summer_N.htm?csp=34> (8/29) reports, "If global warming continues as expected, the blistering heat of this past July will be commonplace in less than 50 years, a University of Montana climate expert predicts. Steve Running, a forestry professor and one of the authors of an international paper on climate change released this spring, said forecasts predict an average July in 2050 will be like the parching, record-breaking July of 2007, with triple-digit temperatures common."

Hello Dr Ruedy,

My name is Michael Cassin. I'm developing some technology for hosting online datasets and statistical analysis, and would like to inquire about the possibility of reproducing the GISS temperature data. I realise it is available through the web interface, but would like to know if there is an ftp, or other, site where the entire dataset can be downloaded. I'd also like to be sure of any copyright issues.

Apologies for the direct intrusion into your inbox. I would understand if you redirect my inquiry.

Best regards,

Mike Cassin

Reto,

Here is another request. There are many charges out there that we are hiding the computer code and refuse to give it up. It would be very foolish not to provide what we have now. Below is the response that I would like to give -- is it o.k. -- please improve or suggest any changes that you think it should have.

Jim

You are welcome to have a copy of our computer code. You are not the only one who has asked for it. Depending upon your programming background, there is a possible small complication in that parts of the computer program as it is used were written by a person (Jay Glascoe) who left several years ago in a code (Java????) that is obscure to most of us (perhaps all of us at GISS). Reto Ruedy is in the process of rewriting that part in Fortran, as we know the function of it; and the Java and Fortran codes should give the same results. In the interim, we will release the codes as they have been used (including Jay's Java subroutines). The procedure to access will be described in my next e-mail, which I will send this week.

Dear Dr. Hansen,

My name is _____ and I am a graduate student in physics at UC Berkeley. I am writing to request the complete computer program source code you and your coauthors used to adjust and analyze the surface temperature data in the following paper:

Hansen, J., Mki. Sato, R. Ruedy, K. Lo, D.W. Lea, and M. Medina-Elizade 2006. Global temperature change. Proc. Natl. Acad. Sci. 103, 14288-14293,
<http://www.pnas.org/cgi/content/abstract/103/39/14288>

I and others would like to understand all details of your analysis of global temperature trends. I am making this request for source code consistent with the PNAS policy copied below.

Thank you very much in advance.

Sincerely,

PNAS policy from <http://www.pnas.org/misc/iforc.shtml#policies>

(viii) Materials and Data Availability. To allow others to replicate and build on work published in PNAS, authors must make materials, data, and associated protocols available to readers. Authors must disclose upon submission of the manuscript any restrictions on the availability of materials or information.

Authors must make Unique Materials (e.g., cloned DNAs; antibodies; bacterial, animal, or plant cells; viruses; and computer programs) promptly available on request by qualified researchers for their own use. Failure to comply will preclude future publication in the journal. It is reasonable for authors to charge a modest amount to cover the cost of preparing and shipping the requested material. Contact pnas@nas.edu if you have difficulty obtaining materials.

(By the way, Reto also notes that the codes are a collection that accumulated over 25 years. Actually, I started with an NYU undergraduate student in the 1970s, but Sergej Lededeff replaced most of that code in the early 1980s. Reto says that he intends to simplify/combine steps in the code, but it may be several weeks before he can do that.)

Subject: Re: DATA correction to surface temperatures
From: "James Hansen" <jhansen@giss.nasa.gov>
Date: Wed, 5 Sep 2007 20:30:09 -0400
To: kesten <canalzero2004@yahoo.com.mx>
CC: James.E.Hansen@nasa.gov

Kesten,

Mc is conducting a pr campaign. There was a minor oversight in in the data processing, due the same stations being in WMO and NOAA data streams but our processing program not recognizing that NOAA had done some adjustments to U.S. stations based on "metadata", while the WMO data was unadjusted. So when the series were hooked together (the NOAA data only going up to 2000) there was a discontinuity which averaged 0.15C over the U.S. and 0.003C. The impact on global temperature was entirely negligible. Contrary to the misinformation that was encouraged in the rightwing media (I cannot understand why conservatives are not the ones standing up for preserving creation -- really wierd -- I guess it has something to do with \$\$), it did not even change the rankings of top temperatures in the U.S. We have always had 1934 and 1998 as a statistical tie. In the only paper (2001) in which we looked at U.S. temperatures we had 1934 warmer by an insignificant one or two hundredths of a degree and we still have that. The method is described very clearly in the literature, but in order to avoid any appearance of holding anything back we are releasing the computer codes (this week, I hope, it is first priority for Reto). You can find the 1987, 1999, 2001 papers describing the method (very simple) on www.giss.nasa.gov -- look under publications and my name. I have to run now but will forward you something later.

Jim Hansen

On 9/5/07, kesten <canalzero2004@yahoo.com.mx> wrote:

Hi Dr. Hansen,

I'm a journalist with CFBX news in Kamloops BC, working on a piece about global warming science and the journalism surrounding it.

I heard about the correction to NASA data suggested by Steve McIntyre from an interview with yourself on CBC radio. You ended by suggesting that the change was insignificant to the body of climate change evidence, and yet, the re-ordering of US temperature record years seemed fairly significant to my ears. Afterwards I read an article suggesting that it doesn't affect the global trends.

Reports (and McIntyre) suggest that McIntyre has to reverse-engineer the data crunching methods of the Goddard Institute. I'm curious as to why this should be necessary. Is the methodology not published or given in sufficient detail for others to check the data? Did you receive requests from McIntyre for data or methods?

I visited the GISS website: <http://data.giss.nasa.gov/gistemp/> and was surprised to find no mention of the data correction nor McIntyre. The issue received quite a bit of media attention up here.

McIntyre and right wing institutes like the Fraser Institute have also made criticisms about IPCC's peer review process. The lack of publication of reviewer's comments. Significant re-writing by beurocrats. Is there anywhere the process is described in more detail than the introduction to the IPCC summary,

any source for such reviewer's comments?

I'm trying to establish to what extent the scientific community is in agreement on the issue. I would expect a certain healthy level of dissent among the 2000 contributors and the authors and reviewers. Where does one find the dissenting opinion from within the IPCC process?

I have a bachelors in math and physics, so feel free to reference any primary published material and statistical methodologies.

thanks for your time,

kesten

CC: "Makiko Sato" <makis@giss.nasa.gov>, "Darnell Cain" <dcain@giss.nasa.gov>

Reto, Robert,

We are getting more and more questions as to why we will not release our temperature data analysis programs. We need to make these available this week, by the end of the day tomorrow.

Can you put these in a place where they are accessible, with an address that I will put in an e-mail? This will be as part of an e-mail that also provides access to the revised "Peak Oil" paper.

It probably should include a simple listing of the function of each subroutine. We can note that a simplified version of the programs will be available in the future.

Finally we need:

- (1) a list of the stations that we remove, and
- (2) line graph of global mean land-ocean temperature index with and without these stations removed (the draft that you gave me has No Corrections, Current Web, No Cleaning -- what do these three categories mean? I believe what we want is two curves, one that uses the data without alterations and one for what we present to the public
- (3) maps showing the results with and without our changes -- the four maps that you made for 1880-2006 are fine, but the maps need to be made with Makiko's program/color scale etc. Also I would like to add two maps: delete the two maps on the left (which show the effect of St Helena/Lihue) and add the result when South America and Africa are replace with no data, the objective being to see how these continents contribute to the global mean temperature change. Clearly the data in those continents is pretty lousy, but how much difference does that make for the global mean?

Jim

Subject: Re: Program release

Jim,

I understand the need to make the programs and input files available. But to put out an unusable product (though it works on our machines, based on the directory structures, compilers, etc. of the various machines) that has to be repeatedly changed may be counterproductive. I wish I had another week - or at least a weekend where I could work without interruption.

(1) As far as list of stations we remove is concerned, most are removed or remain unused automatically because their records are too short to have sufficient overlap with the dominating stations. Do you only want a list of those stations that are explicitly removed at the beginning of the process due to their strange data ?

(2) Corrections: We correct 2 stations (St.Helena and Lihue) and use USHCN instead of the corresponding GHCN data. The rest is dropping parts or all of a record (=cleaning). Hence:

"no corrections"="not correcting the 2 stations, not using USHCN, no cleaning",

"current"="2 corrections+USHCN+cleaning",

"no cleaning"="2 corrections+USHCN".

Are any 2 of these 3 options what you need ?

I guess (3) can be done by Makiko, if not let me know.

Yes, the perception is, unfortunately, what counts now. We will have to release them with the very strong recommendation that anyone wishing to actually use them should wait until they are cleaned up, with the estimate that this will take another week or so (is that the appropriate estimate to give?).

Yes, the list should be those stations explicitly removed, since that is perhaps the most subjective thing that we do to the data, other than the procedures for analysis that are described in the papers.

The "current" result is one of the results that we want to illustrate. For the other, I was thinking of excluding the correction of two stations and not dropping the stations that are on the list of removed stations (some of them might get removed by the analysis program, but that is o.k., it is using objective criteria). If you do not have this, but have something that includes it, for example also replacing USHCN of "current" with WMO, that should be all right.

The objective is to show that our partially subjective choice of stations to remove does not significantly alter the global warming that we obtain. A second objective is to show that the admittedly large problems with African and South American data does not significantly alter the inferred global warming (this second objective just requires Makiko to omit those areas).

Jim

Reto's write-up is excellent. I only want to re-write the introductory couple of paragraphs. How should I do that? This is not a format that I have worked in -- can/should I copy and put in Word?? Jim

The C programs mentioned are actually compiled C "extensions" which are used by the Python programs. I was able to install a copy of these extensions on Web2 in the spring two years ago when we managed to transfer the various GISTEMP CGI scripts from Web1 to Web2, but unfortunately I do not have any record of what special hoops I had to jump through in order to do so.

As for the database system, the Python programs save the station data in binary files using Berkeley DB. The version of BDB on the machine Jay and on the machine Web2 is different.

I have been able to get a Python script which combines station data records to run on Web2, but there are some differences in the resulting output files when compared with the files generated on Jay. I am currently trying to figure out what might be the cause of that, and whether it might be a result of the difference in BDB versions.

Makiko,

Please work on making nice looking maps with global temperature trends for the periods 1880-recent and 1900-recent, for the three cases "current", ""no cleaning"", and "South America and Africa blank". By ""no cleaning"", what I was hoping for was the same as "current" but with the stations on our "no call" list excluded, which means exclude St Helena, the Hawaii station, and the others that our cleaning catches. I am not sure if we have exactly that result.

Jim

On 9/7/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Robert,

I combined all source codes according to the steps I outlined in my documentation and put it on jay:/gcm/GHCN/GISTEMP_sources . Please take a look at it - I tested most pieces. Maybe you find a better way to organize the thing.

The documentation "gistemp.txt" is not the final version. The whole thing is only about 5 MB.

Subject: draft e-mail

From: "James Hansen" <jhansen@giss.nasa.gov>

Date: Fri, 7 Sep 2007 17:50:37 -0400

To: "makiko Sato" <makis@giss.nasa.gov>, "Reto Ruedy" <cdrar@giss.nasa.gov>, "Robert B. Schmunk" <rschmunk@giss.nasa.gov>

here is draft e-mail. I am still writing the 'history' introduction to the program listing.

"Peak Oil" Paper Revised and Temperature Analysis Code

To be removed from Jim Hansen's e-mail distribution respond with REMOVE in subject line.

(1) The paper "Implications of 'Peak Oil' for Atmospheric CO₂ and Climate", recently revised and resubmitted to *Environmental Research Letters*, is available at XXXXXXXXXXXXX.

A principal concern of both referees was our use of a pulse-response function, fit to the Bern carbon cycle model, as opposed to a detailed carbon cycle model. We have clarified limitations of a pulse-response function, but frankly we consider the simplicity and transparency of this approach to be a merit, not a fault. We are concerned mainly with scenarios that have a chance of avoiding "dangerous" CO₂ levels, in which case the strong positive feedbacks found in some climate-carbon models are less likely, and in any case such feedbacks only add to the dichotomy between scenarios with declining emissions and "business-as-usual" scenarios.

We have minimized reference to a "dangerous" atmospheric CO₂ level to satisfy one of the referees. We retained one reference to our recent papers, which are published in peer-reviewed journals and, we believe, make a strong case that we are already close to a dangerous CO₂ level.

The principal conclusion of this paper is that it is possible to keep atmospheric CO₂ at a much lower limit than commonly assumed, provided that coal use is phased out except where the CO₂ is captured and stored. This paper provides some of the rationale for the discussion in "Old King Coal II".

(2) Temperature Analysis Code

Reto Ruedy has organized into a single document as well as practical on a short time scale the programs that produce our global temperature analysis from publicly available data streams of temperature measurements. These are a combination of subroutines written over the past few decades by Sergej Lebedeff, Jay Glascoe, and Reto. Because the programs include a variety of languages and computer unique functions Reto would have preferred to have a week or two to combine these into a simpler more transparent structure, but because of a recent flood of demands for the programs, they are being made available as is. People interested in science may want to wait a week or two for a simplified version.

An introduction to the program description defines the scientific purposes. We have also made a few graphs that may help clarify the significance (or lack thereof) of criticisms in the blogosphere. The one aspect of our procedure where subjectivity could come into play is the choice of which stations are eliminated from the record. This is based on identifying the (small fraction of) stations that raise a red flag (e.g., deviation of 5 standard deviations are more, or a large temporal discontinuity, as defined in our papers). I compared the records of these stations were compared with records of the nearest stations;

if these displayed similar features the records were retained. We provide here the list of stations eliminated.

Figure 1 shows maps of the 1880-2006 and 1900-2006 changes of global temperature with and without these stations, and Figure 2 shows the global mean temperature with and without these stations. The effect is practically imperceptible and clearly insignificant.

Another favorite target of those who would raise doubt about the reality of global warming is the lack of quality data from South America and Africa, a legitimate concern. You will note in our maps of temperature change some blotches in South America and Africa, which are probably due to bad data. Our procedure does not throw out data because it looks unrealistic, as that would be subjective. But what is the global significance of these regions of exceptionally poor data? As shown by Figure 1, omission of South America and Africa has only a tiny effect on the global temperature change. Indeed, where it makes a difference it increases the temperature change by (an entirely insignificant) 0.01C.

This is all the time that I intend to give to this subject, but in case you wonder why we subject ourselves to the shenanigans, there are scientific reasons, repeated here from the "history" introduction to the program description.

"Peak Oil" Paper Revised and Temperature Analysis Code

To be removed from Jim Hansen's e-mail distribution respond with REMOVE in subject line.

(1) The paper "Implications of 'Peak Oil' for Atmospheric CO₂ and Climate", recently revised and resubmitted to *Environmental Research Letters*, is available at XXXXXXXXXXXXXXXX.

A principal concern of both referees was our use of a pulse-response function, fit to the Bern carbon cycle model, as opposed to a detailed carbon cycle model. We have clarified limitations of a pulse-response function, but frankly we consider the simplicity and transparency of this approach to be a merit, not a fault. We are concerned mainly with scenarios that have a chance of avoiding "dangerous" CO₂ levels, in which case the strong positive feedbacks found in some climate-carbon models are less likely, and in any case such feedbacks only add to the dichotomy between scenarios with declining emissions and "business-as-usual" scenarios.

We have minimized reference to a "dangerous" atmospheric CO₂ level to satisfy one of the referees. We retained one reference to our recent papers, which are published in peer-reviewed journals and, we believe, make a strong case that we are already close to a dangerous CO₂ level.

The principal conclusion of this paper is that it is possible to keep atmospheric CO₂ at a much lower limit than commonly assumed, provided that coal use is phased out except where the CO₂ is captured and stored, and use of unconventional fossil fuels is also accompanied by CO₂ capture and storage. This paper provides some of the rationale for the discussion in "Old King Coal II".

(2) Temperature Analysis Code

Reto Ruedy has organized into a single document as well as practical on a short time scale the programs that produce our global temperature analysis from publicly available data streams of temperature measurements. These are a combination of subroutines written over the past few decades by Sergej Lebedeff, Jay Glascoe, and Reto. Because the programs include a variety of languages and computer unique functions Reto would have preferred to have a week or two to combine these into a simpler more transparent structure, but because of a recent flood of demands for the programs, they are being made available as is. People interested in science may want to wait a week or two for a simplified version.

[Why not wait a week before sending this out? Lack of instant response to a request, even lack of a response in negative time, seems to be sufficient reason for international announcements. Steve McClintock stated on a radio program on September XX that GISS refused to give him our computer program. We have a series of e-mails between him and Reto showing that the request came the following day. The objectives here do not seem to be science.]

An introduction to the program description defines the scientific purposes. We have also made a few graphs that may help clarify the significance (or lack thereof) of criticisms in the blogosphere. The one aspect of our procedure where subjectivity could come into play is the

choice of which stations are eliminated from the record. This is based on identifying the (small fraction of) stations that raise a red flag (e.g., deviation of 5 standard deviations or more, or a large temporal discontinuity, as defined in our papers). The records of these stations were compared with records of the nearest neighboring stations; if neighboring stations displayed similar features the records were retained. We provide here the list of stations eliminated.

Figure 1 shows maps of the 1880-2006 and 1900-2006 changes of global temperature with and without these stations, and Figure 2 shows the global mean temperature with and without these stations. The effect is practically imperceptible and clearly insignificant.

Another favorite target of those who would raise doubt about the reality of global warming is the lack of quality data from South America and Africa, a legitimate concern. You will note in our maps of temperature change some blotches in South America and Africa, which are probably due to bad data. Our procedure does not throw out data because it looks unrealistic, as that would be subjective. But what is the global significance of these regions of exceptionally poor data? As shown by Figure 1, omission of South America and Africa has only a tiny effect on the global temperature change. Indeed, the difference that omitting these areas makes is to increase the global temperature change by (an entirely insignificant) 0.01C.

This is all the time that I intend to give to this subject, but in case you wonder why we subject ourselves to the shenanigans, there are scientific reasons, repeated here from the "history" introduction to the program description.

GISS Temperature Analysis

History

The basic GISS temperature analysis scheme was defined in the late 1970s by Jim Hansen when a method of estimating global temperature change was needed for comparison with one-dimensional global climate models. Prior temperature analyses, most notably those of Murray Mitchell, covered only 20-90N latitudes. Our rationale was that the number of Southern Hemisphere stations was sufficient for a meaningful estimate of global temperature change, because temperature anomalies and trends are highly correlated over substantial geographical distances. Our first published results (Hansen et al., Climate impact of increasing atmospheric carbon dioxide, *Science* 213, 957, 1981) showed that, contrary to impressions from northern latitudes, global cooling after 1940 was small, and there was net global warming of about 0.4C between the 1880s and 1970s.

Hansen and Lebedeff (Global trends of measured surface air temperature, *J. Geophys. Res.* 92, 13345, 1987) documented the analysis method, showing that the correlation of temperature change was reasonably strong for stations separated by up to 1200 km, especially at middle and high latitudes. They obtained quantitative estimates of the error in annual and 5-year mean temperature change by sampling at station locations a spatially complete data set of a long run of a global climate model, which was shown to have realistic spatial and temporal variability.

This derived error bar only addressed the error due to incomplete spatial coverage of measurements. As there are other potential sources of error, such as urban warming near meteorological stations, etc., many other methods have been used to verify the approximate

magnitude of inferred global warming. These methods include inference of surface temperature change from vertical temperature profiles in the ground (bore holes) at many sites around the world, rate of glacier retreat at many locations, and studies by several groups of the effect of urban and other local human influences on the global temperature record. All of these yield consistent estimates of the approximate magnitude of global warming, which has now increased to about twice the magnitude that we reported in 1981. Still further affirmation of the reality of the warming is its spatial distribution, which shows largest values at locations remote from any local human influence, with a global pattern consistent with that expected for response to global climate forcings (larger in the Northern Hemisphere than the Southern Hemisphere, larger at high latitudes than low latitudes, larger over land than over ocean).

Some improvements in our analysis were made several years ago (*J. Geophys. Res.* **104**, 30997, 1999; **106**, 23947, 2001) including use of satellite-observed night lights to determine which stations in the United States are located in urban and peri-urban areas, the long-term trends of those stations being adjusted to agree with long-term trends of nearby rural stations.

[As you will see in the latter paper we found 1934 and 1998 to be in a statistical tie for warmest U.S. year, 1934 being warmer by an insignificant couple hundredths of a degree. We still find that result. The minor flaw recently found in our data analysis, which affected U.S. temperatures by 0.15C after 2000, did not alter this result. Pundits picking up on this non-story did not get this right, and further they tried to leave the impression that they were talking about global temperature. Ah me.]

You may wonder why we bother to put up with this hassle and the nasty e-mails that it brings. Well, there are at least a couple of good reasons.

First, there is scientific value in having near-real-time global temperature analyses, it is fairly easy to run the analyses as new data comes in each month, and a lot of people tell us that our analysis and presentation is useful to them. There is merit in having more than one group do the analyses because the results differ somewhat. For example, in 2005 we were the only group initially reporting that as being, on global mean, the warmest year in the record. We would not have obtained that result with our method of extrapolating estimates of anomalies out to distances of 1200 km from the nearest station. Later checks with satellite infrared data indicated that our Arctic and Greenland anomalies were, if anything, conservative.

"Peak Oil" Paper Revised and Temperature Analysis Code

To be removed from Jim Hansen's e-mail distribution respond with REMOVE in subject line.

(1) The paper "Implications of 'Peak Oil' for Atmospheric CO2 and Climate", recently revised and resubmitted to Environmental Research Letters, is available at **XXXXXXXXXXXXX**.

A principal concern of both referees was our use of a pulse-response function, fit to the Bern carbon cycle model, as opposed to a detailed carbon cycle model. We have clarified limitations of a pulse-response function, but frankly we consider the simplicity and transparency of this approach to be a merit, not a fault. We are concerned mainly with scenarios that have a chance of avoiding "dangerous" CO2 levels, in which case the strong positive feedbacks found in some climate-carbon models are less likely, and in any case such feedbacks only add to the dichotomy between scenarios with declining emissions and "business-as-usual" scenarios.

We have minimized reference to a "dangerous" atmospheric CO2 level to satisfy one of the referees. We retained one reference to our recent papers, which are published in peer-reviewed journals and, we believe, make a strong case that we are already close to a dangerous CO2 level.

The principal conclusion of this paper is that it is possible to keep atmospheric CO₂ at a much lower limit than commonly assumed, provided that coal use is phased out except where the CO₂ is captured and stored. This paper provides some of the rationale for the discussion in "Old King Coal II".

(2) Temperature Analysis Code

Reto Ruedy has organized into a single document as well as practical on a short time scale the programs that produce our global temperature analysis from publicly available data streams of temperature measurements. These are a combination of subroutines written over the past few decades by Sergej Lebedeff, Jay Glascoe, and Reto. Because the programs include a variety of languages and computer unique functions Reto would have preferred to have a week or two to combine these into a simpler more transparent structure, but because of a recent flood of demands for the programs, they are being made available as is. People interested in science may want to wait a week or two for a simplified version.

An introduction to the program description defines the scientific purposes. We have also made a few graphs that may help clarify the significance (or lack thereof) of criticisms in the blogosphere. The one aspect of our procedure where subjectivity could come into play is the choice of which stations are eliminated from the record. This is based on identifying the (small fraction of) stations that raise a red flag (e.g., deviation of 5 standard deviations are more, or a large temporal discontinuity, as defined in our papers). I compared the records of these stations were compared with records of the nearest

stations; if these displayed similar features the records were retained. We provide here the list of stations eliminated.

Figure 1 shows maps of the 1880-2006 and 1900-2006 changes of global temperature with and without these stations, and Figure 2 shows the global mean temperature with and without these stations. The effect is practically imperceptible and clearly insignificant.

Another favorite target of those who would raise doubt about the reality of global warming is the lack of quality data from South America and Africa, a legitimate concern. You will note in our maps of temperature change some blotches in South America and Africa, which are probably due to bad data. Our procedure does not throw out data because it looks unrealistic, as that would be subjective. But what is the global significance of these regions of exceptionally poor data? As shown by Figure 1, omission of South America and Africa has only a tiny effect on the global temperature change. Indeed, where it makes a difference it increases the temperature change by (an entirely insignificant) 0.01C.

This is all the time that I intend to give to this subject, but in case you wonder why we subject ourselves to the shenanigans, there are scientific reasons, repeated here from the "history" introduction to the program description.

People interested in science may want to wait a week or two for a simplified version. The documentation/programs are at: <http://data.giss.nasa.gov/gistemp/sources/>

An introduction (History) to the program description defines the scientific purposes. We have also made a few graphs that may help clarify the significance (or lack thereof) of criticisms in the blogosphere. The one aspect of our procedure where subjectivity could come into play is the choice of which stations are eliminated from the record. This is based on identifying the (small fraction of) stations that raise a red flag (e.g., deviation of 5 standard deviations or more, or a large temporal discontinuity, as defined in our papers). The records of these stations were compared with records of the nearest neighboring stations; if neighboring stations displayed similar features the records were retained. The documentation lists stations/data eliminated.

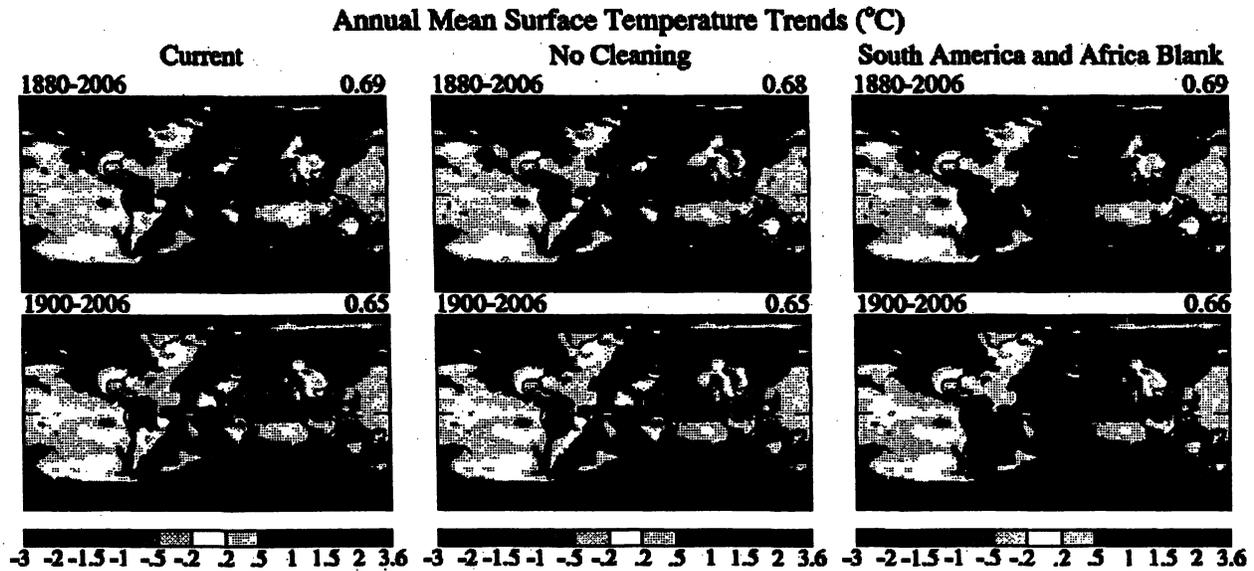

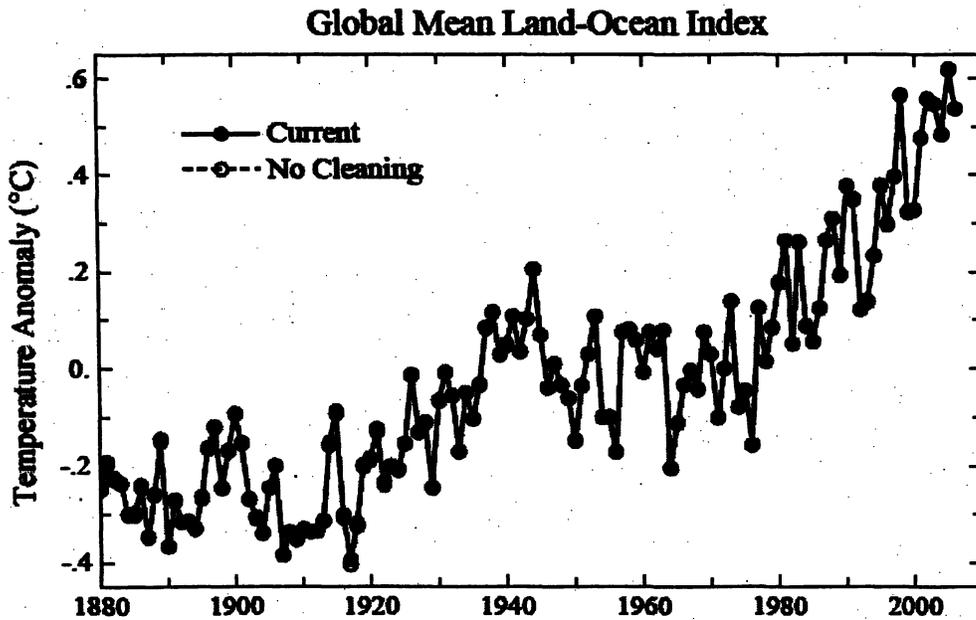

Figure 1 shows maps of the 1880-2006 and 1900-2006 changes of global temperature with and without these stations, and Figure 2 shows the global mean temperature with and without these station/data changes. The effect is practically imperceptible and clearly insignificant.

Another favorite target of those who would raise doubt about the reality of global warming is the lack of quality data from South America and Africa, a legitimate concern. You will note in our maps of temperature change some blotches in South America and Africa, which are probably due to bad data. Our procedure does not throw out data because it looks unrealistic, as that would be subjective. But what is the global significance of these regions of exceptionally poor data? As shown by Figure 1, omission of South America and Africa has only a tiny effect on the global

temperature change. Indeed, the difference that omitting these areas makes is to increase the global temperature change by (an entirely insignificant) 0.01C.

This is all the time that I intend to give to this subject, but in case you wonder why we subject ourselves to the shenanigans, there are scientific reasons, repeated here from the "history" introduction to the program description.

GISS Temperature Analysis

History

The basic GISS temperature analysis scheme was defined in the late 1970s by Jim Hansen when a method of estimating global temperature change was needed for comparison with one-dimensional global climate models. Prior temperature analyses, most notably those of Murray Mitchell, covered only 20-90N latitudes. Our rationale was that the number of Southern Hemisphere stations was sufficient for a meaningful estimate of global temperature change, because temperature anomalies and trends are highly correlated over substantial geographical distances. Our first published results (Hansen et al., Climate impact of increasing atmospheric carbon dioxide, *Science* 213, 957, 1981) showed that, contrary to impressions from northern latitudes, global cooling after 1940 was small, and there was net global warming of about 0.4C between the 1880s and 1970s.

Hansen and Lebedeff (Global trends of measured surface air temperature, *J. Geophys. Res.* 92, 13345, 1987) documented the analysis method, showing that the correlation of temperature change was reasonably strong for stations separated by up to 1200 km, especially at middle and high latitudes. They obtained quantitative estimates of the error in annual and 5-year mean temperature change by sampling at station locations a spatially complete data set of a long run of a global climate model, which was shown to have realistic spatial and temporal variability.

This derived error bar only addressed the error due to incomplete spatial coverage of measurements. As there are other potential sources of error, such as urban warming near meteorological stations, etc., many other methods have been used to verify the approximate magnitude of inferred global warming. These methods include inference of surface temperature change from vertical temperature profiles in the ground (bore holes) at many sites around the world, rate of glacier retreat at many locations, and studies by several groups of the effect of urban and other local human influences on the global temperature record. All of these yield consistent estimates of the approximate magnitude of global warming, which has now increased to about twice the magnitude that we reported in 1981. Still further affirmation of the reality of the warming is its spatial distribution, which shows largest values at locations remote from any local human influence, with a global pattern consistent with that expected for response to global climate forcings (larger in the Northern Hemisphere than the Southern Hemisphere, larger at high latitudes than low latitudes, larger over land than over ocean).

Some improvements in our analysis were made several years ago (*J. Geophys. Res.* 104, 30997, 1999; 106, 23947, 2001) including use of satellite-observed night lights to determine which stations in the United States are located in urban and peri-urban areas, the long-term trends of those stations being adjusted to agree with long-term trends of nearby rural stations.

GISS Temperature Analysis

History

The basic GISS temperature analysis scheme was defined in the late 1970s by Jim Hansen when a method of estimating global temperature change was needed for comparison with one-dimensional global climate models. Prior temperature analyses, most notably those of Murray Mitchell, covered only 20-90N latitudes. Our rationale was that the number of Southern Hemisphere stations was sufficient for a meaningful estimate of global temperature change, because temperature anomalies and trends are highly correlated over substantial geographical distances. Our first published results (Hansen et al., Climate impact of increasing atmospheric carbon dioxide, *Science* 213, 957, 1981) showed that, contrary to impressions from northern latitudes, global cooling after 1940 was small, and there was net global warming of about 0.4C between the 1880s and 1970s.

Hansen and Lebedeff (Global trends of measured surface air temperature, *J. Geophys. Res.* 92, 13345, 1987) documented the analysis method, showing that the correlation of temperature change was reasonably strong for stations separated by up to 1200 km, especially at middle and high latitudes. They obtained quantitative estimates of the error in annual and 5-year mean temperature change by sampling at station locations a spatially complete data set of a long run of a global climate model, which was shown to have realistic spatial and temporal variability.

This derived error bar only addressed the error due to incomplete spatial coverage of measurements. As there are other potential sources of error, such as urban warming near meteorological stations, etc., many other methods have been used to verify the approximate magnitude of inferred global warming. These methods include inference of surface temperature change from vertical temperature profiles in the ground (bore holes) at many sites around the world, rate of glacier retreat at many locations, and studies by several groups of the effect of urban and other local human influences on the global temperature record. All of these yield consistent estimates of the approximate magnitude of global warming, which has now increased to about twice the magnitude that we reported in 1981. Still further affirmation of the reality of the warming is its spatial distribution, which shows largest values at locations remote from any local human influence, with a global pattern consistent with that expected for response to global climate forcings (larger in the Northern Hemisphere than the Southern Hemisphere, larger at high latitudes than low latitudes, larger over land than over ocean).

Some improvements in our analysis were made several years ago (*J. Geophys. Res.* 104, 30997, 1999; 106, 23947, 2001) including use of satellite-observed night lights to determine which stations in the United States are located in urban and peri-urban areas, the long-term trends of those stations being adjusted to agree with long-term trends of nearby rural stations.

[As you will see in the latter paper we found 1934 and 1998 to be in a statistical tie for warmest U.S. year, 1934 being warmer by an insignificant couple hundredths of a degree. We still find that result. The minor flaw recently found in our data analysis, which affected U.S. temperatures by 0.15C after 2000, did not alter this result. Pundits picking up on this non-story did not get this right, and further they tried to leave the impression that they were talking about global temperature. Ah me.]

You may wonder why we bother to put up with this hassle and the nasty e-mails that it brings. Well, there are at least a couple of good reasons.

First, there is scientific value in having a near-real-time global temperature analysis, it is fairly easy to run the program as new data come in each month, and a lot of people tell us that our analysis and presentations are useful to them. There is merit in having more than one group do the analyses because the results differ somewhat. For example, in 2005 we were the only group initially reporting 2005 as being, on global mean, the warmest year in the record. We would not have obtained that result without our method of extrapolating estimates of anomalies out to distances of 1200 km from the nearest station. Later checks with satellite infrared data indicated that our Arctic and Greenland warm anomalies were, if anything, conservative. And the interactions with the NOAA and British groups have been extremely friendly and fruitful and in the spirit of good science, and good science is fun.

Second, the climate change problem is important.

@gmail.com

The current wind energy generating capacity in the U.S. could prevent the burning of 8.4 million tons of coal at the current utility fuel mix. For each megawatt of wind energy produced, 2,000 tons of carbon dioxide greenhouse gases are avoided, 10 tons of sulfur dioxide and 6 tons of nitrogen oxide.

Power generated from coal and other fossil fuels, and the extraction of these fossil fuels have had, and will continue to have, impacts on birds. For example, more than 3,000 birds were killed by collisions during one night in fall migration at a four-smokestack Florida coal-fired power plant. Hundreds of thousands of birds were killed in the Exxon Valdez oil spill and thousands of acres of habitat were damaged.

ABC's Global Climate Change Program documents the significant changes in store for many migratory bird species in this century due to fossil fuel burning. Without a significant change in electrical power conservation and/or a major shift to alternative fuels, the U.S. is projected to increase its greenhouse carbon dioxide emissions between 2001 and 2025 by 43.5 percent. Global warming is predicted to cause changes in the ranges of birds, disruption of migration timing and synchrony with food resources. Avian species and some ecosystems may

be threatened. For a state by state analyses of the effects on birds,
go to ABC's web site at: [http://www.abcbirds.org/climatechange/
statepage.htm](http://www.abcbirds.org/climatechange/statepage.htm) and access The Birdwatcher's Guide to Global Warming.

'Peak Oil' Paper Revised and Temperature Analysis Code

(1) The paper "Implications of 'Peak Oil' for Atmospheric CO₂ and Climate", recently revised and resubmitted to *Environmental Research Letters*, is available at http://pubs.giss.nasa.gov/abstracts/submitted/Kharecha_Hansen.html

A principal concern of both referees was our use of a pulse-response function, fit to the Bern carbon cycle model, as opposed to a detailed carbon cycle model. We have clarified limitations of a pulse-response function, but frankly we consider the simplicity and transparency of this approach to be a merit, not a fault. We are concerned mainly with scenarios that have a chance of avoiding "dangerous" CO₂ levels, in which case the strong positive feedbacks found in some climate-carbon models are less likely, and in any case such feedbacks only add to the dichotomy between scenarios with declining emissions and "business-as-usual" scenarios.

We have minimized reference to a "dangerous" atmospheric CO₂ level to satisfy one of the referees. We retained one reference to our recent papers, which are published in peer-reviewed journals and, we believe, make a strong case that we are already close to a dangerous CO₂ level.

The principal conclusion of this paper is that it is possible to keep atmospheric CO₂ at a much lower limit than commonly assumed, provided that coal use is phased out except where the CO₂ is captured and stored, and use of unconventional fossil fuels, if it occurs, is also accompanied by CO₂ capture and storage. This paper provides some of the rationale for the discussion in "Old King Coal II": http://www.columbia.edu/~jeh1/distro_OldKingCoallI_70730.pdf

(2) Temperature Analysis Code

Reto Ruedy has organized into a single document, as well as practical on a short time scale, the programs that produce our global temperature analysis from publicly available data streams of temperature measurements. These are a combination of subroutines written over the past few decades by Sergej Lebedeff, Jay Glascoe, and Reto. Because the programs include a variety of languages and computer unique functions, Reto would have preferred to have a week or two to combine these into a simpler more transparent structure, but because of a recent flood of demands for the programs, they are being made available as is. People interested in science may want to wait a week or two for a simplified version. The documentation/programs are at: <http://data.giss.nasa.gov/gistemp/sources/>

An introduction (History) to the program description defines the scientific purposes. We have also made a few graphs that may help clarify the significance (or lack thereof) of criticisms in the blogosphere. The one aspect of our procedure where subjectivity could come into play is the choice of which stations are eliminated from the record. This is based on identifying the (small fraction of) stations that raise a red flag (e.g., deviation of 5 standard deviations or more, or a large temporal discontinuity, as defined in our papers). The records of these stations were compared with records of the nearest neighboring stations; if neighboring stations displayed similar features the records were retained. The documentation lists stations/data eliminated.

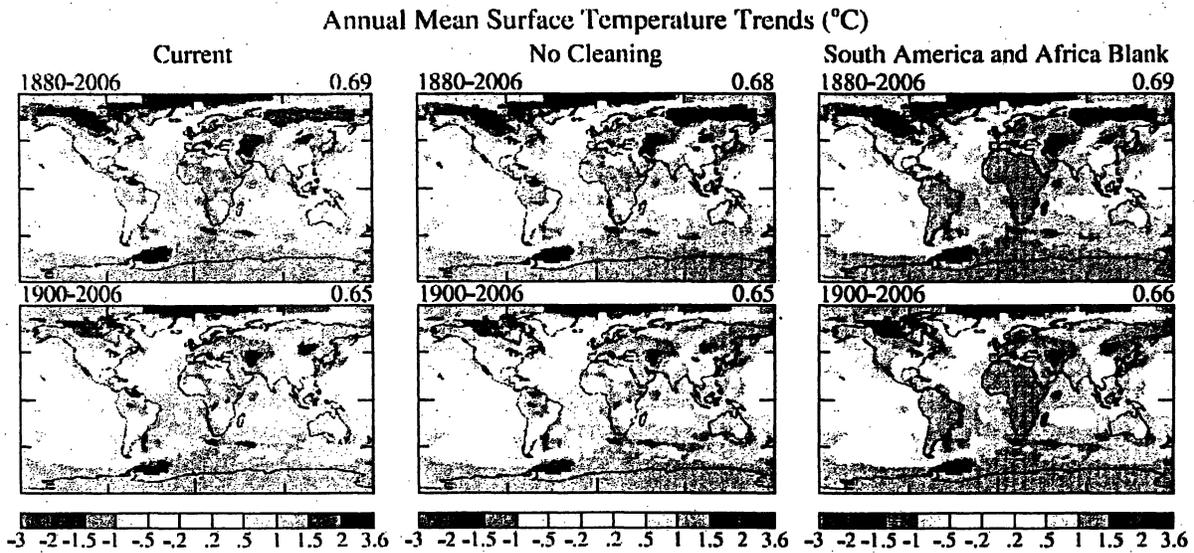

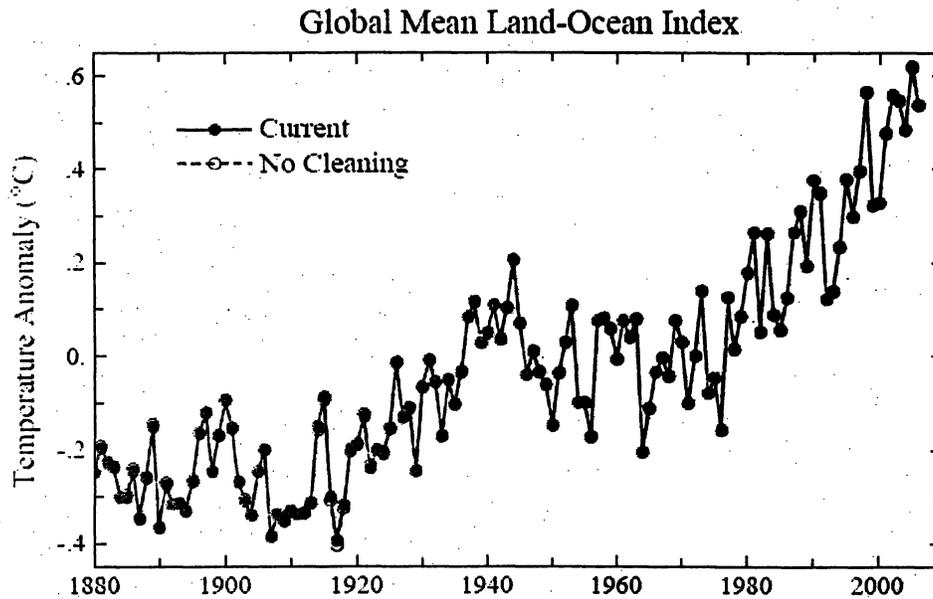

Figure 1 shows maps of the 1880-2006 and 1900-2006 changes of global temperature with and without these stations, and Figure 2 shows the global mean temperature with and without these station/data changes. The effect is practically imperceptible and clearly insignificant.

Another favorite target of those who would raise doubt about the reality of global warming is the lack of quality data from South America and Africa, a legitimate concern. You will note in our maps of temperature change some blotches in South America and Africa, which are probably due to bad data. Our procedure does not throw out data because it looks unrealistic, as that would be subjective. But what is the global significance of these regions of exceptionally poor data? As shown by Figure 1, omission of South America and Africa has only a tiny effect on the global

temperature change. Indeed, the difference that omitting these areas makes is to increase the global temperature change by (an entirely insignificant) 0.01C.

This is all the time that I intend to give to this subject, but in case you wonder why we subject ourselves to the shenanigans, there are scientific reasons, repeated here from the "history" introduction to the program description.

GISS Temperature Analysis

History

The basic GISS temperature analysis scheme was defined in the late 1970s by Jim Hansen when a method of estimating global temperature change was needed for comparison with one-dimensional global climate models. Prior temperature analyses, most notably those of Murray Mitchell, covered only 20-90N latitudes. Our rationale was that the number of Southern Hemisphere stations was sufficient for a meaningful estimate of global temperature change, because temperature anomalies and trends are highly correlated over substantial geographical distances. Our first published results (Hansen et al., Climate impact of increasing atmospheric carbon dioxide, *Science* 213, 957, 1981) showed that, contrary to impressions from northern latitudes, global cooling after 1940 was small, and there was net global warming of about 0.4C between the 1880s and 1970s.

Hansen and Lebedeff (Global trends of measured surface air temperature, *J. Geophys. Res.* 92, 13345, 1987) documented the analysis method, showing that the correlation of temperature change was reasonably strong for stations separated by up to 1200 km, especially at middle and high latitudes. They obtained quantitative estimates of the error in annual and 5-year mean temperature change by sampling at station locations a spatially complete data set of a long run of a global climate model, which was shown to have realistic spatial and temporal variability.

This derived error bar only addressed the error due to incomplete spatial coverage of measurements. As there are other potential sources of error, such as urban warming near meteorological stations, etc., many other methods have been used to verify the approximate magnitude of inferred global warming. These methods include inference of surface temperature change from vertical temperature profiles in the ground (bore holes) at many sites around the world, rate of glacier retreat at many locations, and studies by several groups of the effect of urban and other local human influences on the global temperature record. All of these yield consistent estimates of the approximate magnitude of global warming, which has now increased to about twice the magnitude that we reported in 1981. Still further affirmation of the reality of the warming is its spatial distribution, which shows largest values at locations remote from any local human influence, with a global pattern consistent with that expected for response to global climate forcings (larger in the Northern Hemisphere than the Southern Hemisphere, larger at high latitudes than low latitudes, larger over land than over ocean).

Some improvements in our analysis were made several years ago (*J. Geophys. Res.* 104, 30997, 1999; 106, 23947, 2001) including use of satellite-observed night lights to determine which stations in the United States are located in urban and peri-urban areas, the long-term trends of those stations being adjusted to agree with long-term trends of nearby rural stations.

[As you will see in the latter paper we found 1934 and 1998 to be in a statistical tie for warmest U.S. year, 1934 being warmer by an insignificant couple hundredths of a degree. We still find that result. The minor flaw recently found in our data analysis, which affected U.S. temperatures by 0.15C after 2000, did not alter this result. Pundits picking up on this non-story did not get this right, and further they tried to leave the impression that they were talking about global temperature. Ah me.]

You may wonder why we bother to put up with this hassle and the nasty e-mails that it brings. Well, there are at least a couple of good reasons.

First, there is scientific value in having a near-real-time global temperature analysis, it is fairly easy to run the program as new data come in each month, and a lot of people tell us that our analysis and presentations are useful to them. There is merit in having more than one group do the analyses because the results differ somewhat. For example, in 2005 we were the only group initially reporting 2005 as being, on global mean, the warmest year in the record. We would not have obtained that result without our method of extrapolating estimates of anomalies out to distances of 1200 km from the nearest station. Later checks with satellite infrared data indicated that our Arctic and Greenland warm anomalies were, if anything, conservative. And the interactions with the NOAA and British groups have been extremely friendly and fruitful and in the spirit of good science, and good science is fun.

Second, the climate change problem is important.

We should make the explanation about switching to newer USHCN available. But I don't think that changes should be made that affect the results, even at the 0.00x level, unless/until we discuss it when I am in the office. A machine dependence is not something that we can be assaulted for, but changing the analysis in response to McIntyre adds fuel to the bonfire of his vanities. Jim

On 9/12/07, **Reto Ruedy** <rruedy@giss.nasa.gov> wrote:

Jim,

Steve is still having fun with step0, but eventually he'll find that we did not document how we determined the US brightness numbers we use in our homogeneization.

Checking that step, I noticed that the program that reads Stutzer's file is machine dependent, because some stations lie on the edge between 2 cells. If in these cases I use the brighter of the 2 cells the choices become more robust. 8 of the about 400 rural stations would become peri-urban, and since we don't distinguish between urban and peri-urban stations, these would be the only effective changes.

I looked at the US annual mean series in both cases: they differ by less than .003 C except between 1880 and 1900; in 1900 the difference new-old is -0.005C, in 1880 +.014C .

I would prefer to use add the newer version into the sources. I'd also like to take the text out of the tar file and make it available separately - this is probably the only thing that any normal person might be interested in. The big brightness file should probably also be stored separately for the convenience of those who would just want to look at the programs.

By the way, Steve's newest "discovery" about the Detroit file is simply due to our switch from USHCN-1999 to USHCN-2005.

He also claims (not in any email, just in his blogs - so it may not be true), USHCN-2006 is also available; I know that NOAA has it but I can't find it on the USHCN site.

Got Makiko's phone message. I agree that we need to add a dated statement to a list each time we change the analysis procedure or input files that are used. This can be a very brief statement. In the present case a simple statement to the effect that we switched to XXX on yyy. If WMO or NCDC changes the data in a file, that is not our change, but when we make a change it should be noted.

I believe that the statement that the USHCN data were updated with the 2005 data available from such-and-such website should be accompanied by line graphs of the U.S. and global temperature showing the results before and after. Jim

On 9/12/07, Makiko Sato <makis@giss.nasa.gov> wrote:

Reto,

Yes, now I remember that you had told me that USHCN data were cleaned more, dropping many stations which Jim had eliminated. I was just forgetting about it when I talked with Jim on the phone just before I left work. I am sorry.

Now my question is that

when you were using USHCN through 1999 and switching to GHCN from 2000, you matched the GHCN and USHCN means for 1990-1999, right?

now when you use USHCN through 2005 and use GHCN for 2006 and 2007, do you match the GHCN and USHCN means for 1996-2005?

It is getting late, so I hope you go home soon and I will ask you tomorrow.

Good night,
Makiko

See suggestion below:

On 9/13/07, Makiko Sato <makis@giss.nasa.gov> wrote:

Jim,

I made comparisons of the old data and the new data and put them at the top of [http://www.giss.nasa.gov/~makis/GISS Temp/](http://www.giss.nasa.gov/~makis/GISS_Temp/) where others can't see.

Reto made a good point. He says I should not use the words "USHCN through 1999" and "USHCN through 2005" but "USHCN 2000 version" and "USHCN current version". He is right because the newer version not just go through 2005 but also they cleaned data for 1880-1999. But do you think it is clear if I write "2000 version" and "current version"? Maybe I should add a sentence describing "2000 version" is through 1999 and the current version is through 2005? How do you want it?

How about:

USHCN 2000 Version (data through 1999)
USHCN Current Version (data through 2005)

I can wait to put this on the web (for the public) tomorrow.

Makiko

Hi David, September 19 I am in . September 21 would work but I have several interviews that day that do not end until mid afternoon, so you would need to stay for a late afternoon discussion. September 25 could work, in between some other discussions, on the 24th and 26th I will not be in office (at Clinton Initiative on the 26th - you could come to that, but fee is \$15,000 - they waived it for me).

Jim

Dear Jim,

Bob Cahalan has asked me to travel to GISS to interview you directly so that we can produce an article for NASA's Earth Observatory about this topic, clarifying your important work in monitoring global surface temperature trends for the public.

Looking at my schedule, I can take the train to New York next week on either September 19 or 21; or the following week on either September 24, 25, or 26. Would any of those days work for you? Please advise as soon as possible so I can make travel arrangements.

I am looking forward to it.

Best regards,

David Herring

Subject: Temp Page

From: James Hansen <jhansen@giss.nasa.gov>

Date: Fri, 14 Sep 2007 19:49:27 -0400

To: Makiko Sato <makis@giss.nasa.gov>, Reto Ruedy <rueedy@giss.nasa.gov>, Robert Schmunk <rschmunk@giss.nasa.gov>

Here is new text for the Web. Some inserts and corrections are needed. The change made in April 2006 is unintelligible. As indicated, it needs to include links to several graphs/maps made by Makiko. Some parts of this, such as the Background probably need to be via link -- but perhaps these sections should start out with the first few lines and then to a link for the whole section?? All of the items in the list of changes to the analysis should be included, but perhaps just the first line or so then... to a link??

Jim

TempPage.doc	Content-Type: application/msword Content-Encoding: base64
---------------------	--

History

The basic GISS temperature analysis scheme was defined in the late 1970s by Jim Hansen when a method of estimating global temperature change was needed for comparison with one-dimensional global climate models. Prior temperature analyses, most notably those of Murray Mitchell, covered only 20-90N latitudes. Our rationale was that the number of Southern Hemisphere stations was sufficient for a meaningful estimate of global temperature change, because temperature anomalies and trends are highly correlated over substantial geographical distances. Our first published results (Hansen et al., Climate impact of increasing atmospheric carbon dioxide, *Science* 213, 957, 1981) showed that, contrary to impressions from northern latitudes, global cooling after 1940 was small, and there was net global warming of about 0.4C between the 1880s and 1970s.

Hansen and Lebedeff (Global trends of measured surface air temperature, *J. Geophys. Res.* 92, 13345, 1987) documented the analysis method, showing that the correlation of temperature change was reasonably strong for stations separated by up to 1200 km, especially at middle and high latitudes. They obtained quantitative estimates of the error in annual and 5-year mean temperature change by sampling at station locations a spatially complete data set of a long run of a global climate model, which was shown to have realistic spatial and temporal variability.

This derived error bar only addressed the error due to incomplete spatial coverage of measurements. As there are other potential sources of error, such as urban warming near meteorological stations, etc., many other methods have been used to verify the approximate magnitude of inferred global warming. These methods include inference of surface temperature change from vertical temperature profiles in the ground (bore holes) at many sites around the world, rate of glacier retreat at many locations, and studies by several groups of the effect of urban and other local human influences on the global temperature record. All of these yield consistent estimates of the approximate magnitude of global warming, which has now increased to about twice the magnitude that we reported in 1981. Still further affirmation of the reality of the warming is its spatial distribution, which shows largest values at locations remote from any local human influence, with a global pattern consistent with that expected for response to global climate forcings (larger in the Northern Hemisphere than the Southern Hemisphere, larger at high latitudes than low latitudes, larger over land than over ocean).

Some improvements in our analysis were made several years ago (*J. Geophys. Res.* 104, 30997, 1999; 106, 23947, 2001) including use of satellite-observed night lights to determine which stations in the United States are located in urban and peri-urban areas, the long-term trends of those stations being adjusted to agree with long-term trends of nearby rural stations.

Current Analysis Method

The current analysis uses surface air temperatures measurements from the following data sets: the unadjusted data of the Global Historical Climatology Network (Peterson and Vose, 1997 and 1998), United States Historical Climatology Network (USHCN) records through 2005, and SCAR (Scientific Committee on Antarctic Research) data from Antarctic stations. The basic analysis method is described by Hansen et al. (1999), with several modifications described by Hansen et al. (2001) also included. The GISS analysis is updated monthly.

We modify the GHCN/USHCN/SCAR data in two steps to obtain station data from which our tables, graphs, and maps are constructed: in step 1, if there are multiple records at a given location, these are combined into one record; in step 2 we adjust the urban stations so that their long-term trend matches that of the mean of neighboring rural stations. Urban stations without nearby rural stations are dropped.

A global temperature index, as described by Hansen et al. (1996), is obtained by combining the meteorological station measurements with sea surface temperatures based in early years on ship measurements and in recent decades on satellite measurements. Uses of this data should credit the original sources, specifically the British HadISST group (Rayner, XXXX, and others) and the NOAA satellite analysis group (Reynolds, Smith and others). (See references.)

Our analysis is limited to the period since 1880 because of poor spatial coverage of stations and decreasing data quality prior to that time. Meteorological station data provide a useful indication of temperature change in the Northern Hemisphere extratropics for a few decades prior to 1880, and there are a small number of station records that extend back to previous centuries. However, we believe that analyses for these earlier years need to be carried out on a station by station basis with an attempt to discern the method and reliability of measurements at each station, a task beyond the scope of our analysis. Global studies of still earlier times depend upon incorporation of proxy measures of temperature change. References to such studies are provided in Hansen et al. (1999).

Programs used in the GISTEMP analysis and documentation on their use are available for download. The programs assume a Unix-like operating system and require familiarity with FORTRAN, C and Python for installation.

Updates to Analysis

Several minor updates to the analysis have been made since its last published description by Hansen et al. (2001).

August 2003: a longer version of Hohenpeissenberg station was made available to GISS and added to the GHCN record. This had no noticeable impact on the global analyses.

March 2005: SCAR data were added to the analysis. This increased data coverage over Antarctica, as evident in the global maps of temperature anomalies.

April 2006: A mask for ocean data applied to data after 1982 was applied to the whole series.

August 2007: A discontinuity in station records in the U.S. was discovered and corrected (GHCN data for 2000 and later years were inadvertently appended to USHCN data for prior years without including the adjustments at these stations that had been defined by the NOAA National Climate Data Center). This had a small impact on the U.S. average temperature, about 0.15C, for 2000 and later years, and a negligible effect on global temperature.

This August 2007 change received international attention via discussions on various blogs, and repetition by some other media, with no graphs provided to show the magnitude of the effect. We provide [here](#) graphs showing the effect on U.S. and global temperature. Discussions of the curious misinformation are provided [HERE](#) and [HERE](#). (links to the discussions on Columbia web page)

September 2007: The year 2000 version of USHCN data was replaced by the current version (with data through 2005). In this newer version NOAA removed a number of stations that did not satisfy quality control checks. The stations removed by NOAA in the newer version included all of those that had failed our quality control check, so our analysis program no longer removes any U.S. stations from USHCN records. Our quality control is described by Hansen et al. (2001) and all stations removed by it are available in a [list](#). The effect of station removal on analyzed global temperature is very small, as shown by graphs and maps [available here](#).

Annual Summations

NASA news releases about the GISS surface temperature analysis are available for 2006, 2005, and 2004.

We also provide here discussions of global surface temperature trends for 2005, 2004, 2003, 2002, and 2001.

Table Data: Global and Zonal Mean Anomalies dT_s

Anomaly values indicate difference from the corresponding 1951-1980 means.

Table of global-mean monthly, annual and seasonal dT_s , based on met.station data, 1880-present, updated through most recent month

Table of N. Hemi-mean monthly, annual and seasonal dT_s , based on met.station data, 1880-present, updated through most recent month

Table of S. Hemi-mean monthly, annual and seasonal dT_s , based on met.station data, 1880-present, updated through most recent month

Table of global-mean monthly, annual and seasonal land-ocean temperature index, 1880-present, updated through most recent month

Table of zonal-mean annual dT_s , 1880-present, updated through most recent completed year

Table of zonal-mean annual land-ocean temperature index, 1880-present, updated through most recent completed year

Gridded Monthly Maps of Temperature Anomaly Data

Users interested in the entire gridded temperature anomaly data may download the three basic binary files from our ftp site. Also available there are two sample FORTRAN programs, "SBBX_to_1x1.f" and "sbbx2nc.f", which demonstrate how you can extract gridded anomaly files for any month and year from the larger datasets.

Data files for individual years may be obtained from the ftp site's subdirectories: bin for binary format, txt for ASCII text, and netcdf for netCDF. However, these files are updated irregularly and the latest year or two of annual data might not be available.

Anomalies and Absolute Temperatures

Our analysis concerns only temperature anomalies, **not** absolute temperature. Temperature anomalies are computed relative to the base period 1951-1980. The reason to work with anomalies, rather than absolute temperature is that absolute temperature varies markedly in short distances, while monthly or annual temperature anomalies are representative of a much larger region. Indeed, we have shown (Hansen and Lebedeff, 1987) that temperature anomalies are strongly correlated out to distances of the order of 1000 km. For a more detailed discussion, see *The Elusive Absolute Surface Air Temperature*.

Not quite sure what locations are being referred to, but we need to have all key info on the first page of GISTEMP. What I am hoping is that Rob can make a clever way of having everything important there in a small enough space, e.g., by starting out with the first few lines of paragraph of a section that is completed in an attachment. Thus the main page will direct users to the important results, with an indication of what they include.

I can see why the public has been confused as we presently offer practically no identifiable explanation of recent changes.

I think that it is important to put this stuff up soon. It does not need to be the final format and the list of changes does not have to be complete. But try to avoid putting up something that is later embarrassing.

We thought about it, but the difference in (a) and (c) are, for (c) there is no write-ups, and for (a) if you click, you can see graphs right away, so we just mentioned they show graphs and maps.

> The section after "what's new" might profit from being titled "How does

With suggested editing below, I believe that this should allow a complete version of the new front page to GISTEMP. I think that you should go ahead and replace it without waiting for me to get back from Jim

On 9/15/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Jim,

In the description of step2 (homogeneization) "urban" should be replaced by "urban and peri-urban" or "non-rural" or we may add a sentence to indicate that "small-town" stations are adjusted the same way as urban stations. Although it is mentioned at the end of the previous section, it should probably be repeated here to avoid accusations of inconsistency.

let's use: "urban and peri-urban (i.e., other than rural)"
that makes an unambiguous definition of our categories

April 2006 modification:

Looking at maps based on ocean data alone, we noticed that the HadISST data (1880-1981) extended to regions containing sea ice, whereas the NOAA data (1982-present) did not. In order to get a more consistent time series, the HadISST part was restricted to the same ice-free regions as the NOAA data. Since the temperature of water containing ice is always near the freezing point, including data from such regions tends to artificially dampen any heating or cooling trend.

April 2006 modification: HadISST ocean temperatures are now used only for regions that are identified as ice-free in both the NOAA and HadISST records. This change effects a small number of gridboxes in which HadISST has sea ice while NOAA has open water. The prior approach damped temperature change at these gridboxes because of specification of a fixed temperature in sea ice regions. The new approach still yields a conservative estimate of surface air temperature change, as surface air temperature usually changes markedly when sea ice is replaced by open water or vice versa. Because of the small area of these gridboxes the effect on global temperature change was negligible.

Great. It is not so long as I feared, let's use it this way. In the August 2003 item put "station data" where it presently says "station". In the August 2007 item replace the sentence "We provide here..." with Graphs showing the effect of this change on U.S. and global temperature are available here.

I think that you can put them up temporarily with the direct links to the Columbia web page, and later replace that to a link to just the graphs and discussion of the graphs extracted from the Columbia web page and placed in a GISS repository. That specific discussion of graphs should also note that discussion of the significance of the changes is included on the Columbia web site giving the location (and perhaps also the RealClimate location?) of the web site (it can just be the web site, without going directly to the articles on GISTEMP). I understand your concern, but to ignore the misinformation is also a concern.

On 9/16/07, Robert B. Schmunk <Robert.B.Schmunk@nasa.gov> wrote:

A preliminary re-working of the GISTEMP homepage is at

http://data.giss.nasa.gov/gistemp/index_new.html

Although very long, it could go up as-is in place of the current GISTEMP homepage except that the links to the Columbia webpage stuff are not there yet (i.e., in the second para of the Aug 2007 update comments).

I am very concerned about linking directly to the PDFs on the Columbia webpage, whether here or on the graphs page as Makiko has already done, because it is transparent to the user that the PDFs are located on Jim's personal webpage. All they know is that they click on a link on a NASA webpage and they get a PDF. Hence the inattentive user (which would be most of them) would think the PDF is a NASA document.

So on Sunday I will try to make a pass through the PDFs and extract out the material which can be posted on a NASA webpage. I would assume this would mostly mean toning down or eliminating language re: skeptics and denialists.

Also, Makiko, I cleaned up the HTML of the "what's new" you put at the start of the graphs webpage. Is the "(a)", "(b)", "(c)" notation necessary? I left it there, but can't see that it needs to be there.

Also, Makiko, I cleaned up the HTML of the "what's new" you put at the start of the graphs webpage. Is the "(a)", "(b)", "(c)" notation necessary? I left it there, but can't see that it needs to be there.

Yes, you can make that change. Of course what I meant was in the places that mattered, Wall Street Journal, etc. there was no proper indication of the magnitude or relevance of the effect. Jim

On 9/17/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

Jim,

We could fix this by changing "magnitude of the effect" by "relevance of the effect" which is obviously what you meant. Not that this will prevent him from further maligning us.

I cannot do both. Significant work requires blocks of time. I have been doing this long enough to know that I can accomplish almost nothing if I have an hour in the morning, then interview, then check out, afternoon there will be other things, relatives. I will be glad to do the interview in the afternoon, preferably the early afternoon. I am presently sufficiently worried about past due dates that I am up now at 3 AM
Jim

On 9/17/07, "[@gustavus.edu](#)> wrote:

Jim,

You have much more experience with the media than I so you are probably not surprised that we got a call earlier today indicating that we will need to inform MPR today if you are willing to have the in-studio interview on Monday, October 1, at 10 a.m. I know this is not your preferred time but I do hope that you can both accommodate this time and maximize this "free" day to accomplish the work you plan on attending to.

Regardless of your decision, can you please let me know today?

Thanks.

Subject: Re: Regarding the criticisms of McIntyre et al

You make some good points. I think of my response as a blunt statement of the truth, but others can view it as editorializing. It is 3 AM so I just note that we did thank Mc He has tried to mislead in several ways. We only make changes that make scientific sense, and we should not stop doing that. We have now listed those on the first page of the temperature web page.

Regarding the question of editorializing...I did a lot of soul searching before noting in a talk two years ago that the global warming story was being distorted by special interests ..my Keeling talk at AGU ...most people now believe that this was a good thing to do...if we just report the science and do not make note of misinformation, it is not clear that the message gets out, and we are running out of time.

Jim Hansen

On 9/18/07, @sbsoft.com> wrote:

Dear Sir:

I don't understand your recent approach in dealing with the recent criticisms of Steve McIntyre and friends.

As you recently noted (and McIntyre agrees), none of these criticisms have a material effect on global temperature.

The credibility of GISS (and other organizations aggregating temperature data) DOES have a material impact on any analysis of global temperature.

If McIntyre shows that you have an agenda, then your data (and the conclusions supported by your data) are weakened.

By making undocumented changes to your methodology (which McIntyre subsequently dissects on his blog) you provide ammunition to those who insist that you have agenda, and that your agenda is tainting your data.

Why not adopt an ultraconservative approach in all of the changes that you make? Why not:

1. avoid making changes except in the case of outright errors
2. publicly document all changes at the time they occur
3. graciously thank McIntyre et al for any errors they bring to your attention

4. avoid making editorial statements, and let the data speak for itself.

It makes no difference whether 1934 or 1998 was warmer in the United States. But your recent statements and changes have created the impression that GISS cares about this issue, and is willing to change its methodology accordingly.

It makes little difference whether or not this is true. What matters is whether or not you have created a trail of data that would allow an observer to reach the conclusion that your agenda has impacted your actions.

I think you have, and that this is infinitely more damaging than a temperature adjustment here or there.

Sincerely,

Leslie,

I am in Denmark at a meeting on Arctic climate change, trying to convince scientists of the Arctic nations (I guess England is not included) that reduction of non-CO2 forcings, with a slowdown of CO2 emissions, could stabilize Arctic and global climate.

However, Mr. Ritchotte should be made aware that the minor flaw found in processing of 2000-2007 data did not alter the warmest years of U.S temperature and certainly not global temperature. This story was a mountain from a molehill constructed by global warming deniers. The actual story, and the misinformation, are available via the GISS web page, www.giss.nasa.gov - click on Data and Images and then on GISS Surface Temperature analysis.

Subject: Re: Possible story about the temp record

David,

As the time we have to talk today may be limited, let me note a couple of things here:

I wrote a discussion for the GISS web page that should clarify the situation including the (in)significance of the recent minor flaw in the data stream. Please look at that discussion.

Note that the tactic of people such as the science fiction writer and the recent fellow is to focus on details without global understanding and insight. Of course if one looks at several thousand stations one can find some with flaws, but those flaws work in both directions (the one potentially large bias in one direction, urban warming, is dealt with explicitly).

These topics should be dealt with in some overall way without getting drawn into detail, as the latter is the aim of those who wish to confuse and deny the reality of global warming.

Rather an article should focus on the warming itself, e.g., a map of the anomalies for the first several years of this century. all of the major features on this map (greater warming in NH than SH, greater warming over land than ocean, Arctic warming, Antarctic Peninsula, etc. make sense physically and are expected due to increasing GHGs.

It is also important to put this in the longer time context. Thus the (two-part) graph in our recent PNAS paper [Makiko has an alternative, probably better, version to the published one] showing the paleo records and modern data together for the key regions of Indian Ocean and Pacific Warm Pool is quite important.

These important matters can be connected to the 'data flaw' story by the fact that the data flaw has no impact on them whatever.

Subject: Preliminary examination of HL87 bias method as applied to individual station records
To: James.E.Hansen@nasa.gov

Dear Dr. Hansen,

I understand you are extremely busy, but I wanted to pass along some analysis I have been doing on your method of combining individual temperature records for a single station using the "bias method", as described primarily in HL87.

My preliminary analysis of the method seems to show that it introduces an "artificial cooling" to station records before 1987. This cooling seems to be introduced primarily as a result of two things: the order selected for combining records and the fact that annual and quarterly temperatures are estimated prior to combining those records.

In HL87 you acknowledge: "One potential disadvantage of the method we have described for combining station records is that the results, in principle, depend on the ordering of the station records." However, the discussion that ensues is around different stations rather than different records for the same station. I am finding that, when using this method to combine records from a single station, the ordering of records has far more influence than expected.

The descriptions I have seen for ordering stations in your papers indicate that they are ordered from greatest number of years of temperature record to the least number of years. In practice what I find is that if an MCDW (Monthly Climatic Data for the World) record exists, it is used first, even though it is usually the shortest record (when it exists, it also the latest record for a station). Because it is the first record in the order, it is never biased, but all others preceding it chronologically are biased. The overlap period with preceding records seems to be somewhat short - usually four years, sometimes five. Although HL87 discusses the combination of stations within a gridcell, the implication is that the same methodology is used for combining station records. This would mean the minimum overlap period should be 20 years.

In reading HL87 I would have expected the period of overlap to be calculated using the months of overlap, which represents the finest grain of measurement in the record GISS uses. Instead, I have determined that the annual record is used, which is the coarsest grain of measurement in the record used by GISS. If the monthly records were complete, this would not be an issue. In practice I find that they are usually not complete, so an

estimated annual average is often used when determining overlap periods. In fact, the first year in a record is almost always an estimate. This is because the records begin in January, but the average is calculated from December to November. Thus, the "missing" December value must be estimated. The process of estimating annual averages prior to combining individual records for a station is not one that I have found documented thus far.

As chance would have it, the process of combining records using MCDW records first, the short overlap period between MCDW records and previous records, and the fact that many annual averages are estimated, seems to yield a clear cooling bias to pre-1991 temperature records. An example can be seen here with the Russian records.

While I understand the rationale behind using the bias method to combine station records within a grid cell, I don't fully understand why it is used to combine separate records for an individual station. As you note in your 1999 paper "in the majority of cases the overlapping portions of the two records are identical, representing the same measurements that have made their way into more than one data set." This indicates that a simple average of the records is appropriate.

Why is the bias method better than the following?:

- For each station examine all monthly records for the station simultaneously
- If no valid measurement exists in any record for a given month, record NA (or equivalent)
- If exactly one valid measurement exists for a given month, use that value
- If more than one valid measurement exists for a given month, use the average of all valid measurements

After all records have been combined in this manner, estimate missing annual values where possible.

I appreciate your thoughts on this.

Hmm - it seems that I didn't check very closely what Jay was doing. Some of the choices do not seem to be the way that we intended them to be. It looks like we had better fix those and see what difference it makes. I thought that we started with the longest record? There could be a rationale for starting with the closest record, and, if it was shown that it didn't matter, perhaps there is a rationale for something different. Jim

On 9/28/07, Reto Ruedy <rriedy@giss.nasa.gov> wrote:
Jim,

I dealt with him yesterday since some station graphs no longer appeared (probably as a consequence of some errors in the program used to automatically create the station data tables - a program he subsequently corrected). I had to clean out the work directory to make the utilities function again.

His inquiry and response definitely lacked McIntyre's haughty and aggressive tone. But we did not get into any discussions.

As far as his comments are concerned, I don't exactly remember how much freedom we gave Jay to design the procedure to combine station records at the same location and how much testing he did.

In the bias procedure used to combine anomaly series, we use a separate bias for each month, Jay uses a single annual bias to combine temperature series at the same location, but we require a shorter overlap period in that case (4 years vs 20 years - maybe that's why we made the switch from monthly to annual bias).

I don't remember why Jay ranked stations with respect to their sources and always starts with MCDW-data if such data are available rather than using length only - maybe for reasons of continuity (before using GHCN, MCDW was our main source).

I doubt very much that the specific way to handle multiple records matters as far as US or global mean series are concerned. That our method introduces no systematic bias is confirmed by the fact that our and NOAA's totally different approach gives virtually the same answers.

I remember that in the regular case we tried closeness and length of record and decided that length of record was more important. Jim

On 9/28/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

In our gridding program, we combine the records strictly according to length of records. Closeness might be an alternative, but a station near the center of a subgrid box with a 20-year record might create a short time series for that subbox based on a single station.

In Jay's case, closeness is moot, since all records refer to the same location.

Hi

Thanks for the comments and suggestions. I spoke briefly with Reto. He has looked into the routine written by Jay Glascoe to combine records, and although its a language he is not familiar with, he says that he can at least make the simple changes needed to test the ordering of stations. Since we tested the ordering of stations in the main part of the program (we are not sure whether Jay rechecked that), we doubt that it would make a noticeable difference, but will let you know.

We didn't have time to discuss the other things yet. But I note that tests in the past have shown such choices to have small impact.

Regards, Jim Hansen

On 9/27/07, @charter.net> wrote:
Dear Dr. Hansen,

I understand you are extremely busy, but I wanted to pass along some analysis I have been doing on your method of combining individual temperature records for a single station using the "bias method", as described primarily in HL87.

My preliminary analysis of the method seems to show that it introduces an "artificial cooling" to station records before 1987. This cooling seems to be introduced primarily as a result of two things: the order selected for combining records and the fact that annual and quarterly temperatures are estimated prior to combining those records.

In HL87 you acknowledge: "One potential disadvantage of the method we have described for combining station records is that the results, in principle, depend on the ordering of the station records." However, the discussion that ensues is around different stations rather than different records for the same station. I am finding that, when using this method to combine records from a single station, the ordering of records has far more influence than expected.

The descriptions I have seen for ordering stations in your papers indicate that they are ordered from greatest number of years of temperature record to the least number of years. In practice what I find is that if an MCDW (Monthly Climatic Data for the World) record exists, it is used first, even though it is usually the shortest record (when it exists, it also the latest record for a station). Because it is the first record in the order, it is never biased, but all others preceding it chronologically are biased. The overlap period with preceding records seems to be somewhat short - usually four years, sometimes five. Although HL87 discusses the combination of stations within a gridcell, the implication is that the same methodology is used for combining station records. This would mean the minimum overlap period should be 20 years.

In reading HL87 I would have expected the period of overlap to be calculated using the months of overlap, which represents the finest grain of measurement in the record GISS uses. Instead, I have determined that the

annual record is used, which is the coarsest grain of measurement in the record used by GISS. If the monthly records were complete, this would not be an issue. In practice I find that they are usually not complete, so an estimated annual average is often used when determining overlap periods. In fact, the first year in a record is almost always an estimate. This is because the records begin in January, but the average is calculated from December to November. Thus, the "missing" December value must be estimated. The process of estimating annual averages prior to combining individual records for a station is not one that I have found documented thus far.

As chance would have it, the process of combining records using MCDW records first, the short overlap period between MCDW records and previous records, and the fact that many annual averages are estimated, seems to yield a clear cooling bias to pre-1991 temperature records. An example can be seen here with the Russian records.

While I understand the rationale behind using the bias method to combine station records within a grid cell, I don't fully understand why it is used to combine separate records for an individual station. As you note in your 1999 paper "in the majority of cases the overlapping portions of the two records are identical, representing the same measurements that have made their way into more than one data set." This indicates that a simple average of the records is appropriate.

Why is the bias method better than the following?:

- For each station examine all monthly records for the station simultaneously
- If no valid measurement exists in any record for a given month, record NA (or equivalent)
- If exactly one valid measurement exists for a given month, use that value
- If more than one valid measurement exists for a given month, use the average of all valid measurements

After all records have been combined in this manner, estimate missing annual values where possible.

I appreciate your thoughts on this.

Gavin,

In 2000, USHCN provided us with a product in which the US data were adjusted for changes in procedure/instrumentation to get a consistent time record. According to the description on their current website, 1999 was their last comprehensive update of those data. Unlike the GHCN data, the USHCN data are not routinely kept up-to-date (at this point the seem to end in 2002).

Under the assumption that the adjustments made the older data consistent with future data, we are replacing the US part of the GHCN data up to 1999 by the USHCN data that we got in 2000, thereby eliminating some known systematic biases in the early part of the US records.

However, that assumption may not have been correct. I compared the 1999 data in GHCN and USHCN. Indeed, in 490 of the 1057 stations the USHCN data were up to 1C colder than the corresponding GHCN data, in 77 stations the data were the same, and in the remaining 490 stations the USHCN data were warmer than the GHCN data. The differences averaged out to 0.1 C, i.e. we may have introduced a +0.1C jump in 2000 over the US by our procedure.

A more careful method would have been to compare the last few years of the USHCN data and the corresponding years of the GHCN data and adjust the USHCN data to fit the GHCN data. I'll add this procedure as an alternate to see what effect it would have.

There is something curious here though, why does 'GISS raw' go back to 'USHCN unadjusted' in 2000. Shouldn't it have stayed with USHCN+TOBS?

Gavin

PS. if this is all as it should be, we need to make clear the reasons why very quickly. Otherwise, the myth of the 'Hansen Y2k error' will be all around the place and once it's out, it won't go away.

On 9/18/07, @sbsoft.com> wrote:

Dear Sir:

I don't understand your recent approach in dealing with the recent criticisms of Steve McIntyre and friends.

As you recently noted (and McIntyre agrees), none of these criticisms have a material effect on global temperature.

The credibility of GISS (and other organizations aggregating temperature data) DOES have a material impact on any analysis of global temperature.

If McIntyre shows that you have an agenda, then your data (and the conclusions supported by your data) are weakened.

By making undocumented changes to your methodology (which McIntyre subsequently dissects on his blog) you provide ammunition to those who insist that you have agenda, and that your agenda is tainting your data.

Why not adopt an ultraconservative approach in all of the changes that you make? Why not:

1. avoid making changes except in the case of outright errors
2. publicly document all changes at the time they occur
3. graciously thank McIntyre et al for any errors they bring to your attention

4. avoid making editorial statements, and let the data speak for itself.

It makes no difference whether 1934 or 1998 was warmer in the United States. But your recent statements and changes have created the impression that GISS cares about this issue, and is willing to change its methodology accordingly.

It makes little difference whether or not this is true. What matters is whether or not you have created a trail of data that would allow an observer to reach the conclusion that your agenda has impacted your actions.

I think you have, and that this is infinitely more damaging than a temperature adjustment here or there.

Sincerely,

Leslie,

I am in Denmark at a meeting on Arctic climate change, trying to convince scientists of the Arctic nations (I guess England is not included) that reduction of non-CO2 forcings, with a slowdown of CO2 emissions, could stabilize Arctic and global climate.

However, Mr. Ritchotte should be made aware that the minor flaw found in processing of 2000-2007 data did not alter the warmest years of U.S temperature and certainly not global temperature. This story was a mountain from a molehill constructed by global warming deniers. The actual story, and the misinformation, are available via the GISS web page, www.giss.nasa.gov - click on Data and Images and then on GISS Surface Temperature analysis.

Subject: Re: Possible story about the temp record

David,

As the time we have to talk today may be limited, let me note a couple of things here:

I wrote a discussion for the GISS web page that should clarify the situation including the (in)significance of the recent minor flaw in the data stream. Please look at that discussion.

Note that the tactic of people such as the science fiction writer and the recent fellow is to focus on details without global understanding and insight. Of course if one looks at several thousand stations one can find some with flaws, but those flaws work in both directions (the one potentially large bias in one direction, urban warming, is dealt with explicitly).

These topics should be dealt with in some overall way without getting drawn into detail, as the latter is the aim of those who wish to confuse and deny the reality of global warming.

Rather an article should focus on the warming itself, e.g., a map of the anomalies for the first several years of this century. all of the major features on this map (greater warming in NH than SH, greater warming over land than ocean, Arctic warming, Antarctic Peninsula, etc. make sense physically and are expected due to increasing GHGs.

It is also important to put his in the longer time context. Thus the (two-part) graph in our recent PNAS paper [Makiko has an alternative, probably better, versions to the published one] showing the paleo records and modern data together for the key regions of Indian Ocean and Pacific Warm Pool is quite important.

These important matters can be connected to the 'data flaw' story by the fact that the data flaw has no impact on them whatever.

Subject: Preliminary examination of HL87 bias method as applied to individual station records
To: James.E.Hansen@nasa.gov

Dear Dr. Hansen,

I understand you are extremely busy, but I wanted to pass along some analysis I have been doing on your method of combining individual temperature records for a single station using the "bias method", as described primarily in HL87.

My preliminary analysis of the method seems to show that it introduces an "artificial cooling" to station records before 1987. This cooling seems to be introduced primarily as a result of two things: the order selected for combining records and the fact that annual and quarterly temperatures are estimated prior to combining those records.

In HL87 you acknowledge: "One potential disadvantage of the method we have described for combining station records is that the results, in principle, depend on the ordering of the station records." However, the discussion that ensues is around different stations rather than different records for the same station. I am finding that, when using this method to combine records from a single station, the ordering of records has far more influence than expected.

The descriptions I have seen for ordering stations in your papers indicate that they are ordered from greatest number of years of temperature record to the least number of years. In practice what I find is that if an MCDW (Monthly Climatic Data for the World) record exists, it is used first, even though it is usually the shortest record (when it exists, it also the latest record for a station). Because it is the first record in the order, it is never biased, but all others preceding it chronologically are biased. The overlap period with preceding records seems to be somewhat short - usually four years, sometimes five. Although HL87 discusses the combination of stations within a gridcell, the implication is that the same methodology is used for combining station records. This would mean the minimum overlap period should be 20 years.

In reading HL87 I would have expected the period of overlap to be calculated using the months of overlap, which represents the finest grain of measurement in the record GISS uses. Instead, I have determined that the annual record is used, which is the coarsest grain of measurement in the record used by GISS. If the monthly records were complete, this would not be an issue. In practice I find that they are usually not complete, so an

estimated annual average is often used when determining overlap periods. In fact, the first year in a record is almost always an estimate. This is because the records begin in January, but the average is calculated from December to November. Thus, the "missing" December value must be estimated. The process of estimating annual averages prior to combining individual records for a station is not one that I have found documented thus far.

As chance would have it, the process of combining records using MCDW records first, the short overlap period between MCDW records and previous records, and the fact that many annual averages are estimated, seems to yield a clear cooling bias to pre-1991 temperature records. An example can be seen here with the Russian records.

While I understand the rationale behind using the bias method to combine station records within a grid cell, I don't fully understand why it is used to combine separate records for an individual station. As you note in your 1999 paper "in the majority of cases the overlapping portions of the two records are identical, representing the same measurements that have made their way into more than one data set." This indicates that a simple average of the records is appropriate.

Why is the bias method better than the following?:

- For each station examine all monthly records for the station simultaneously
- If no valid measurement exists in any record for a given month, record NA (or equivalent)
- If exactly one valid measurement exists for a given month, use that value
- If more than one valid measurement exists for a given month, use the average of all valid measurements

After all records have been combined in this manner, estimate missing annual values where possible.

I appreciate your thoughts on this.

Subject: Re: Fwd: Preliminary examination of HL87 bias method as applied to individual station records

Hmm - it seems that I didn't check very closely what Jay was doing. Some of the choices do not seem to be the way that we intended them to be. It looks like we had better fix those and see what difference it makes. I thought that we started with the longest record? There could be a rationale for starting with the closest record, and, if it was shown that it didn't matter, perhaps there is a rationale for something different. Jim

On 9/28/07, Reto Ruedy <rriedy@giss.nasa.gov> wrote:
Jim,

I dealt with him yesterday since some station graphs no longer appeared (probably as a consequence of some errors in the program used to automatically create the station data tables - a program he subsequently corrected). I had to clean out the work directory to make the utilities function again.

His inquiry and response definitely lacked McIntyre's haughty and aggressive tone. But we did not get into any discussions.

As far as his comments are concerned, I don't exactly remember how much freedom we gave Jay to design the procedure to combine station records at the same location and how much testing he did.

In the bias procedure used to combine anomaly series, we use a separate bias for each month, Jay uses a single annual bias to combine temperature series at the same location, but we require a shorter overlap period in that case (4 years vs 20 years - maybe that's why we made the switch from monthly to annual bias).

I don't remember why Jay ranked stations with respect to their sources and always starts with MCDW-data if such data are available rather than using length only - maybe for reasons of continuity (before using GHCN, MCDW was our main source).

I doubt very much that the specific way to handle multiple records matters as far as US or global mean series are concerned. That our method introduces no systematic bias is confirmed by the fact that our and NOAA's totally different approach gives virtually the same answers.

I remember that in the regular case we tried closeness and length of record and decided that length of record was more important. Jim

On 9/28/07, Reto Ruedy <rruedy@giss.nasa.gov> wrote:

In our gridding program, we combine the records strictly according to length of records. Closeness might be an alternative, but a station near the center of a subgrid box with a 20-year record might create a short time series for that subbox based on a single station.

In Jay's case, closeness is moot, since all records refer to the same location.

Hi

Thanks for the comments and suggestions. I spoke briefly with Reto. He has looked into the routine written by Jay Glascoe to combine records, and although its a language he is not familiar with, he says that he can at least make the simple changes needed to test the ordering of stations. Since we tested the ordering of stations in the main part of the program (we are not sure whether Jay rechecked that), we doubt that it would make a noticeable difference, but will let you know.

We didn't have time to discuss the other things yet. But I note that tests in the past have shown such choices to have small impact.

Regards, Jim Hansen

Dear Dr. Hansen,

I understand you are extremely busy, but I wanted to pass along some analysis I have been doing on your method of combining individual temperature records for a single station using the "bias method", as described primarily in HL87.

My preliminary analysis of the method seems to show that it introduces an "artificial cooling" to station records before 1987. This cooling seems to be introduced primarily as a result of two things: the order selected for combining records and the fact that annual and quarterly temperatures are estimated prior to combining those records.

In HL87 you acknowledge: "One potential disadvantage of the method we have described for combining station records is that the results, in principle, depend on the ordering of the station records." However, the discussion that ensues is around different stations rather than different records for the same station. I am finding that, when using this method to combine records from a single station, the ordering of records has far more influence than expected.

The descriptions I have seen for ordering stations in your papers indicate that they are ordered from greatest number of years of temperature record to the least number of years. In practice what I find is that if an MCDW (Monthly Climatic Data for the World) record exists, it is used first, even though it is usually the shortest record (when it exists, it also the latest record for a station). Because it is the first record in the order, it is never biased, but all others preceding it chronologically are biased. The overlap period with preceding records seems to be somewhat short - usually four years, sometimes five. Although HL87 discusses the combination of stations within a gridcell, the implication is that the same methodology is used for combining station records. This would mean the minimum overlap period should be 20 years.

In reading HL87 I would have expected the period of overlap to be calculated using the months of overlap, which represents the finest grain of measurement in the record GISS uses. Instead, I have determined that the

annual record is used, which is the coarsest grain of measurement in the record used by GISS. If the monthly records were complete, this would not be an issue. In practice I find that they are usually not complete, so an estimated annual average is often used when determining overlap periods. In fact, the first year in a record is almost always an estimate. This is because the records begin in January, but the average is calculated from December to November. Thus, the "missing" December value must be estimated. The process of estimating annual averages prior to combining individual records for a station is not one that I have found documented thus far.

As chance would have it, the process of combining records using MCDW records first, the short overlap period between MCDW records and previous records, and the fact that many annual averages are estimated, seems to yield a clear cooling bias to pre-1991 temperature records. An example can be seen here with the Russian records.

While I understand the rationale behind using the bias method to combine station records within a grid cell, I don't fully understand why it is used to combine separate records for an individual station. As you note in your 1999 paper "in the majority of cases the overlapping portions of the two records are identical, representing the same measurements that have made their way into more than one data set." This indicates that a simple average of the records is appropriate.

Why is the bias method better than the following?:

- For each station examine all monthly records for the station simultaneously
- If no valid measurement exists in any record for a given month, record NA (or equivalent)
- If exactly one valid measurement exists for a given month, use that value
- If more than one valid measurement exists for a given month, use the average of all valid measurements

After all records have been combined in this manner, estimate missing annual values where possible.

I appreciate your thoughts on this.

Gavin,

In 2000, USHCN provided us with a product in which the US data were adjusted for changes in procedure/instrumentation to get a consistent time record. According to the description on their current website, 1999 was their last comprehensive update of those data. Unlike the GHCN data, the USHCN data are not routinely kept up-to-date (at this point the seem to end in 2002).

Under the assumption that the adjustments made the older data consistent with future data, we are replacing the US part of the GHCN data up to 1999 by the USHCN data that we got in 2000, thereby eliminating some known systematic biases in the early part of the US records.

However, that assumption may not have been correct. I compared the 1999 data in GHCN and USHCN. Indeed, in 490 of the 1057 stations the USHCN data were up to 1C colder than the corresponding GHCN data, in 77 stations the data were the same, and in the remaining 490 stations the USHCN data were warmer than the GHCN data. The differences averaged out to 0.1 C, i.e. we may have introduced a +0.1C jump in 2000 over the US by our procedure.

A more careful method would have been to compare the last few years of the USHCN data and the corresponding years of the GHCN data and adjust the USHCN data to fit the GHCN data. I'll add this procedure as an alternate to see what effect it would have.

There is something curious here though, why does 'GISS raw' go back to 'USHCN unadjusted' in 2000. Shouldn't it have stayed with USHCN+TOBS?

Gavin

PS. if this is all as it should be, we need to make clear the reasons why very quickly. Otherwise, the myth of the 'Hansen Y2k error' will be all around the place and once it's out, it won't go away.

Jim,

I've started to prepare a response to the email below. Steve is the person who appointed himself the auditor of all web sites and organizations that have to do with global warming in order to debunk this "hoax". He is maintaining a blog - a website called climate.audit.org, a site containing among justified concerns (caveats that we stress in all our papers) obvious fabrications and vicious attacks.

I'll send you my suggestion for a response before mailing anything to Steve.

Our simple combination of GHCN and USHCN data was based on the assumption that the correction made the older data consistent with the then current data. Unfortunately, that is not the case and an attempt to compute an offset based on the common years within say the 1990-1999 period would have been more appropriate.

I am re-processing our current data with that modification and wait with finishing my response until we can look at the changes caused by it. I expect only a minor effect since the offsets average out to almost 0 over all USHCN stations.

I am unaware of any mention of this change in procedure in any published methodological descriptions and am puzzled as to its rationale. Can you clarify this for me?

The basic "GISS Surface Temperature Analysis" page starts with a "Background" section whose first paragraph contains the sentence: "Input data for the analysis , . . . , is the unadjusted data of GHCN, except that the USHCN station records were replaced by a later corrected version". A similar statement appears in the "Abstract" and the "Introduction" section of our 2001 paper (JGR Vol 106, pg 23,947-23,948). The Introduction explains the above statement in more detail.

When we got the USHCN data, they ended in 1999 and as far as I know, no major corrections were implemented after that time. Unlike the GHCN data, the USHCN data is not a product that is kept current on a regular basis. Hence we used (as you noticed) the GHCN data to extend the USHCN data.

I agree with you that this simple procedure creates an artificial step in those cases where the correction was applied to the newest data, rather than bringing the older data in sync with the latest measurements - which would seem the natural way to go. Comparing the 1999 data in both data sets showed that in about half the cases where the 1999 data were changed, the GHCN data were higher than the USHCN data and in the other half it was the other way round.

So although an attempt to eliminate those artificial steps should have little impact even on the US temperature trend (much less the global trend - the so-called "Global Warming"), it seems a good idea to do so and I'd like to thank you for bringing this to our attention.

Starting with our next update (sometime later this week) an offset based on the last 10 years of overlap in the two data sets will be applied and our on-line documentation will be augmented correspondingly.

I tested the modification with the data now on display: The table data (section 3 on the basic temperature site) differed occasionally by a 1 in the last digit (0.01 C). In the display most sensitive to that change - the US-graph of annual means - the warming decreased by about 0.15 C in the years 2000-2006, well within the margin of error.

In addition, could you provide me with any documentation (additional to already published material) providing information on the

| calculation of GISS raw and adjusted series from USHCN versions,
| including relevant source code.

I had no idea what code you are referring to until I learned from your article "Hansen's Y2K error" (which should really be "Reto's Y2K error") that GISS is in possession of some magical software that is able to "fix" the defects in surface data. No wonder you would like to get your hands on that - so would I !

Unfortunately, your source totally misled you in that respect. I'm a little amazed that you uncritically present it as a fact given that a large part of your web site is devoted to convincingly prove that such software cannot possibly exist.

All we do is try to make the best of imperfect data by converting absolute temperatures to anomalies and averaging over large regions (using circles of a diameter of 2400 km, the 500 km option was added for debugging purposes only), the only responsible way to use those data.

The software we spend close to 100% of our time in developing and which is the real basis of our work (in addition to general physics and chemistry), is openly available (giss.nasa.gov/tools/modelE) to anybody.

Dear Sir,

As to the question about documentation, the basic "GISS Surface Temperature Analysis" page starts with a "Background" section whose first paragraph contains the sentence: "Input data for the analysis ,..., is the unadjusted data of GHCN, except that the USHCN station records were replaced by a later corrected version". A similar statement appears in the "Abstract" and the "Introduction" section of our 2001 paper (JGR Vol 106, pg 23,947-23,948). The Introduction explains the above statement in more detail.

In 2000, USHCN provided us with a file with corrections not contained in the GHCN data. Unlike the GHCN data, that product is not kept current on a regular basis. Hence we used (as you noticed) the GHCN data to extend those data in our further updates (2000-present).

I agree with you that this simple procedure creates an artificial step if some new corrections were applied to the newest data, rather than bringing the older data in sync with the latest measurements - as I naively assumed. Comparing the 1999 data in both data sets showed that in about half the cases where the 1999 data were changed, the GHCN data were higher than the USHCN data and in the other half it was the other way round with the plus-corrections slightly outweighing the minus-corrections.

Although trying to eliminate those steps should have little impact on the US temperature trend (much less the global trend), it seems a good idea to do so and I'd like to thank you for bringing this oversight to our attention.

When we did our monthly update this morning, an offset based on the last 10 years of overlap in the two data sets was applied and our on-line documentation was changed correspondingly with an acknowledgment of your contribution. This change and its effect will be noted in our next paper on temperature analysis and in our end-of-year temperature summary.

The effect on global means and all our tables was less than 0.01 C. In the display most sensitive to that change - the US-graph of annual means - the anomalies decreased by about 0.15 C in the years 2000-2006.

Respectfully,

Reto A Ruedy

"Peak Oil" Paper Revised and Temperature Analysis Code

To be removed from Jim Hansen's e-mail distribution respond with REMOVE in subject line.

(1) The paper "Implications of 'Peak Oil' for Atmospheric CO2 and Climate", recently revised and resubmitted to Environmental Research Letters, is available at XXXXXXXXXXXX.

A principal concern of both referees was our use of a pulse-response function, fit to the Bern carbon cycle model, as opposed to a detailed carbon cycle model. We have clarified limitations of a pulse-response function, but frankly we consider the simplicity and transparency of this approach to be a merit, not a fault. We are concerned mainly with scenarios that have a chance of avoiding "dangerous" CO2 levels, in which case the strong positive feedbacks found in some climate-carbon models are less likely, and in any case such feedbacks only add to the dichotomy between scenarios with declining emissions and "business-as-usual" scenarios.

We have minimized reference to a "dangerous" atmospheric CO2 level to satisfy one of the referees. We retained one reference to our recent papers, which are published in peer-reviewed journals and, we believe, make a strong case that we are already close to a dangerous CO2 level.

The principal conclusion of this paper is that it is possible to keep atmospheric CO2 at a much lower limit than commonly assumed, provided that coal use is phased out except where the CO2 is captured and stored. This paper provides some of the rationale for the discussion

in "Old King Coal II".

(2) Temperature Analysis Code

Reto Ruedy has organized into a single document as well as practical on a short time scale the programs that produce our global temperature analysis from publicly available data streams of temperature measurements. These are a combination of subroutines written over the past few decades by Sergej Lebedeff, Jay Glascoe, and Reto. Because the programs include a variety of languages and computer unique functions Reto would have preferred to have a week or two to combine these into a simpler more transparent structure, but because of a recent flood of demands for the programs, they are being made available as is. People interested in science may want to wait a week or two for a simplified version.

An introduction to the program description defines the scientific purposes. We have also made a few graphs that may help clarify the significance (or lack thereof) of criticisms in the blogosphere. The one aspect of our procedure where subjectivity could come into play is the choice of which stations are eliminated from the record. This is based on identifying the (small fraction of) stations that raise a red flag (e.g., deviation of 5 standard deviations are more, or a large temporal discontinuity, as defined in our papers). I compared the records of these stations were compared with records of the nearest stations; if these displayed similar features the records were retained. We provide here the list of stations eliminated.

Figure 1 shows maps of the 1880-2006 and 1900-2006 changes of global temperature with and without these stations, and Figure 2 shows the global mean temperature with and without these stations. The effect is practically imperceptible and clearly insignificant.

Another favorite target of those who would raise doubt about the reality of global warming is the lack of quality data from South America and Africa, a legitimate concern. You will note in our maps of temperature change some blotches in South America and Africa, which are probably due to bad data. Our procedure does not throw out data because it looks unrealistic, as that would be subjective. But what is the global significance of these regions of exceptionally poor data? As shown by Figure 1, omission of South America and Africa has only a tiny effect on the global temperature change. Indeed, where it makes a difference it increases the temperature change by (an entirely insignificant) 0.01C.

This is all the time that I intend to give to this subject, but in case you wonder why we subject ourselves to the shenanigans, there are scientific reasons, repeated here from the "history" introduction to the program description.

Jim,

For our 2001 paper, which includes a discussion of the various USHCN adjustments, we obtained from USHCN their various stages after each adjustment. The first set we obtained in Feb 2000, a slightly corrected version in Dec 2000. Since we did not adapt their filling in scheme and their urban adjustment scheme, we have been using the "SHAP" version obtained in Dec 2000.

>From the USHCN site, anybody can download the TOBS and the FILNET stages, i.e. the one immediately before and the one after "SHAP"; a special request is needed to get SHAP. It seems that these data were extended to 2002 in the mean time.

Is it ok to put our copy of the 12/2000 version of SHAP on our web site or do we need to consult with NOAA before doing so ?

Alternatively, of course, we could go back to using GHCN data only. The effect of that change is described in our 2001 paper as well as on USHCN's website (on <http://cdiac.ornl.gov/epubs/ndp/usncn/ndp019.html#tempdata>); it would decrease the 1900-99 US temperature change by .3 C and have negligible effect on any global trends.

Steve will keep asking me for our "software" and I'm tempted to ignore those requests, since our description of what we do with the data completely describes our procedures.

Dear Dr Ruedy,

Thank you for this information and for the courteous acknowledgement at your website. I can now see where your post-2000 data comes from, but I remain unable to identify a digital source for your data prior to 2000 from available information. I have compared GISS raw to all the archived USHCN versions and have been unable to find a match for US data. In some

cases, the differences are substantial.

Can you provide me with (1) a URL from which the U.S. data prior to 2000 (in the version that you used) can be downloaded. (2) If this is no longer possible due to the passage of time, could you please provide me with a copy of the data that you used (or upload it to an area of your FTP site) and also provide its provenance and date of acquisition? Obviously mere print citations are inadequate for this purpose.

I would like to assess the impact of these modifications on the US and global averages for myself. I would appreciate a copy of the source code used for these calculations.

Regards, Steve McIntyre

Subject: Re: GISS Raw Data

Dear Sir,

As to the question about documentation, the basic "GISS Surface Temperature Analysis" page starts with a "Background" section whose first paragraph contains the sentence: "Input data for the analysis , . . . , is the unadjusted data of GHCN, except that the USHCN station records were replaced by a later corrected version". A similar statement appears in the "Abstract" and the "Introduction" section of our 2001 paper (JGR Vol 106, pg 23,947-23,948). The Introduction explains the above statement in more detail.

In 2000, USHCN provided us with a file with corrections not contained in the GHCN data. Unlike the GHCN data, that product is not kept current on a regular basis. Hence we used (as you noticed) the GHCN data to extend those data in our further updates (2000-present).

I agree with you that this simple procedure creates an artificial step if some new corrections were applied to the newest data, rather than bringing the older data in sync with the latest measurements - as I naively assumed. Comparing the 1999 data in both data sets showed that in about half the cases where the 1999 data were changed, the GHCN data were higher than the USHCN data and in the other half it was the other way round with the plus-corrections slightly outweighing the minus-corrections.

Although trying to eliminate those steps should have little impact on the US temperature trend (much less the global trend), it seems a good idea to do so and I'd like to thank you for bringing this

oversight
to our attention.

When we did our monthly update this morning, an offset based on the last 10 years of overlap in the two data sets was applied and our on-line documentation was changed correspondingly with an acknowledgment of your contribution. This change and its effect will be noted in our next paper on temperature analysis and in our end-of-year temperature summary.

The effect on global means and all our tables was less than 0.01 C. In the display most sensitive to that change - the US-graph of annual means

- the anomalies decreased by about 0.15 C in the years 2000-2006.

Respectfully,

Reto A Ruedy

On Sat, 2007-08-04 at 17:28 -0400, Steve McIntyre wrote:

Dear Sirs,

In your calculation of the GISS "raw" version of USHCN series, it appears to me that, for series after January 2000, you use the USHCN raw version whereas in the immediately prior period you used USHCN time-of-observation or adjusted version. In some cases, this introduces a seemingly unjustified step in January 2000.

I am unaware of any mention of this change in procedure in any published methodological descriptions and am puzzled as to its rationale. Can you clarify this for me?

In addition, could you provide me with any documentation (additional to already published material) providing information on the calculation of GISS raw and adjusted series from USHCN versions, including relevant source code. Thank you for your attention,

Stephen

To: Gavin Schmidt <gschmidt@giss.nasa.gov>

CC: Reto Ruedy <cdrar@giss.nasa.gov>, Jim Hansen <jhansen@giss.nasa.gov>

We might add, that none of the figures in our latest (2001) paper on temperatures was affected, since it was written in 2000, and only data up to 1999 were used for the figures in that paper.

As far as further revisions are concerned, we are considering just using GHCN data (which would reduce the 1900-1999 warming over the US by .3 C and have no noticeable effect on global means).

Needless to say, the whole thing is another red herring.

On Thu, 2007-08-09 at 15:04 -0400, Gavin Schmidt wrote:

I was going to reply thusly, but let me know if you'd rather I left it to you.

Gavin

Andy, this hasn't got much to do with me, but briefly, the issue was as follows. USHCN is a dataset just for the US which has included a number of appropriate corrections to the individual stations based on known site moves and changes in when the data was taken (there has been a shift towards taking data in the morning rather than in the afternoon over the decades). This data is not updated that frequently.

The main source of data is GHCN which is a global product, but that does not take into account the USHCN corrections.

The error was made in assuming that recent values of the GHCN and USHCN were the same. It turns out they weren't and so when the USHCN-corrected stations were extended to the present day using GHCN, there were a number of small jumps (of both sign) in the data. The correction that was put in was then to re-align the GHCN and USHCN data using the 1990-1999 data. This made approximately 0.15 deg C difference in the 2000-2006 period for the US mean, but it is negligible in the global mean. The data were reprocessed and the online values now incorporate that fix.

Given the nature of the error, this is purely a US issue (USHCN doesn't apply to the global data), and as far as I'm aware, no further revisions related to this issue are likely to be forthcoming.

Hi Leslie,

Andy Revkin asked the same question and Jim's answer below says it all in the clearest and most beautiful way.

The blog you attached is a prime example of what gives bloggers a really bad name; somebody with no idea what he is talking about is spouting absolute nonsense, making no distinctions between what is essential (the facts he conveniently omits) and what is pure noise (which he is concentrating on exclusively).

He omits that the global mean time series (which is generally considered the standard measure for global warming) is unaffected

He concentrates on US time series which (US covering less than 2% of the world) is so noisy and has such a large margin of error that no conclusions can be drawn from it at this point; showing the plot of annual means before and after the correction would have made the whole article a joke since the differences are barely visible.

He had to use the device of ranking the years rather than showing the plots to make any point at all. The problem with rankings is that there are large clumps of years which are equal within the margin of error and rankings within these clumps are purely accidental.

He finds it astounding that years 1934 and 1998 reversed ranks, not remembering that the corrections only affected years 2000-2006, hence that there is no possible connection there.

By speaking of warmest year (rather than warmest year in the US time record) he successfully deceived people like Mark Taylor.

Hi Andy,

This seems to be a tempest inside somebody's teapot dome. One of the changes that we made in our analysis in 2001 was to include improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations ARE in the GHCN record, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the

1: Re: revisions to annual temps]

NOAA-corrected records for earlier years caused jumps in the records at those stations, some up, some down.

The net effect averaged over the U.S. was an error of about 0.15C or less in the post-2000 years, well within the uncertainty bar that we give. The effect on the global mean was of the order of a thousandths of a degree, i.e., entirely negligible.

It is unclear why anyone would try to make something out of this, perhaps a light not on upstairs? Or perhaps this is coming from one of the old contrarians? They can't seem to get over the fact that the real world has proven them to be full of malarkey! You would think that they would be ready to crawl under a rock by now!

Jim

Dear Leslie,

My fellow Canadians have unveiled another Global warming scam - yours!

Now that we know Mr. Hansen used incorrect data or procedures in determining the "hottest years", concluding that the top 5 warmest years

since the 1890s are : 2005, 1998, 2002, 2003, 2006.

Yet, there on your website

(<http://www.giss.nasa.gov/research/news/20070208/>) is the information still

making what is now known to be a bogus claim.

Yes we are at a tipping point all right. And the truth is spilling all over your pro-AGW agenda.

Just like Mr. Manns infamous Hockey Stick graph, which was proven fraudulent by the same people who found your glaring errors, another lie bites the dust. Funny thing is, when they determined Mr. Mann was fudging things, they found that Mr. Mann's "peer reviewed" work was reviewed but not put through a rigorous, truth seeking, audit. That led to them forming climateaudit.org, to apply the audits that are so obviously missing from the process. And BINGO - Mr. Hansen is unmasked as a zealot.

Now, are you honestly a scientific driven institution, or will you admit to being an agenda driven one? I await the press conference to announce that you have had to revise the hottest years list. I await the update to your website to reflect the new, peer-audited, results. I await the confession that you made a huge mistake. I await the firing of those who created and flogged this lie.

Will you do the right thing?

Sincerely

Sorry to send another e-mail so soon. No need to read further unless you are interested in temperature changes to a tenth of a degree over the U.S. and a thousandth of a degree over the world.

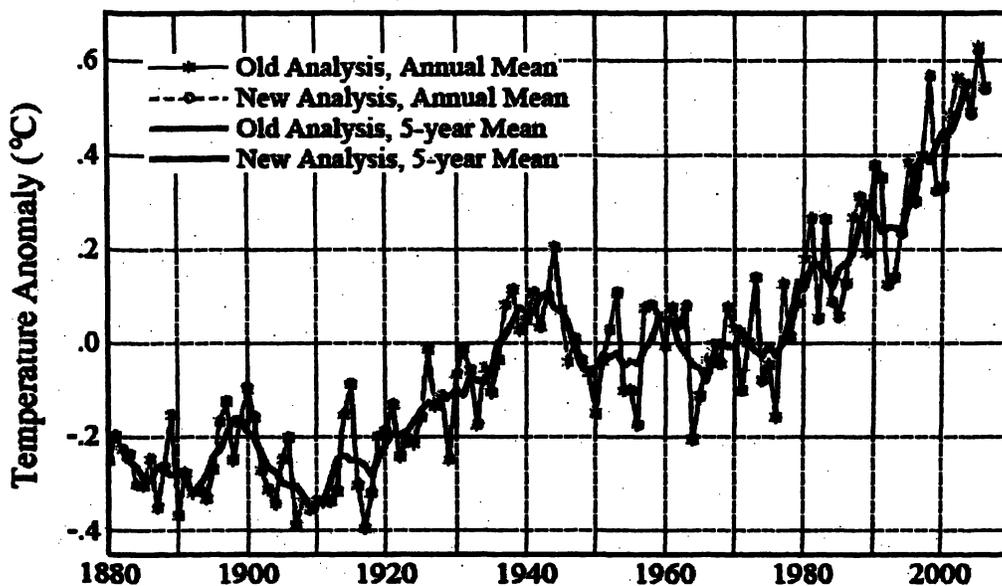

Recently it was realized that the monthly more-or-less-automatic updates of our global temperature analysis (http://pubs.giss.nasa.gov/docs/2001/2001_Hansen_etal.pdf) had a flaw in the U.S. data. In our most recent update of the analysis method (originally published in our 1981 Science paper – http://pubs.giss.nasa.gov/docs/1981/1981_Hansen_etal.pdf) we included improvements that NOAA had made in station records in the U.S., their corrections being based mainly on station-by-station information about station movement, change of time-of-day at which max-min are recorded, etc.

Unfortunately, we didn't realize that these corrections would not continue to be readily available in the near-real-time data streams. The same stations ARE in the GHCN (Global Historical Climatology Network) data stream, however, and thus what our analysis picked up in subsequent years was station data without the NOAA correction. Obviously, combining the uncorrected GHCN with the NOAA-corrected records for earlier years caused jumps in the records at those stations, some up, some down. This problem is easy to fix, by matching the 1990s decadal-mean temperatures for the NOAA-corrected and GHCN records, and we have made that correction.

The flaw did have a noticeable effect on mean U.S. temperature anomalies, as much as 0.15C, as shown in Figure 1 below (for years 2001 and later, and 5 year mean for 1999 and later). The effect on global temperature (Figure 2) was of order one-thousands of a degree, so the corrected and uncorrected curves are indistinguishable.

Global Temperature (Land-Ocean Index)

Somehow this data flaw was advertised on the internet and for two days I have been besieged by rants that I have wronged the President, that I must "step down", or that I must "vanish". Hmm, I am not very good at magic tricks.

I am always a bit puzzled by the views that seem to come from conservative extremes, a bit disconcerting as I come from a moderately conservative state and consider myself a moderate conservative in most ways – puzzling because it seems to me that conservatives should be the first ones standing up for preserving Creation and for the rights of the young and the unborn. After all, that is the basic intergenerational issue in global arming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

My apologies if the quick response that I sent to Andy Revkin and several other journalists, including the suggestion that it was a tempest inside somebody's teapot dome, and that perhaps a light was not on upstairs, was immoderate. It was not ad hominem.

Hi Keith,

We compute these means every month, but since these are annual means, they are copied to the web site only once a year (on February).

So the change that caused all the havoc must have happened after one of the previous routine updates.

Thanks for noticing that,

Reto

On Fri, 2007-08-10 at 17:52 -0400, Keith Winstein wrote:

Thanks, this is very interesting -- even playing this "which is numerically higher" game (if you will indulge that for a bit more), the correction did not affect the relative ordering of the years. 1934 was at 1.25 before and after the correction, and 1998 was at 1.23 before and after the correction.

Do you have any idea why the "before correction" data doesn't match the version that Google downloaded on July 23, 2007 from <http://data.giss.nasa.gov/gistemp/graphs/Fig.D.txt> ?

<http://64.233.169.104/search?q=cache:vskwzroreeQJ:data.giss.nasa.gov/gistemp/graphs/Fig.D.txt+http://data.giss.nasa.gov/gistemp/graphs/Fig.D.txt&hl=en&ct=clnk&cd=1&gl=us&client=firefox-a>

In that version, 1934 was at 1.23 and 1998 was at 1.24.

Perhaps the July 23 2007 version had not yet incorporated the June 2007 data? Any insights would be much appreciated.

In our 2001 paper (JGeophysRes vol 106), which we wrote in 2000 without having access to the full year 2000 data, (bottom of pg 23,958)

The annual US mean temperature is slightly warmer in 1934 than in 1998 in the GISS analysis. This contrasts with the USHCN-adjusted data which has 1998 as the warmest year of the century ...

I talked to the person who does the US calculation every year and she still had the old map series saved. With her program I recomputed the means and indeed: 1934: 1.23 1998: 1.24

And the bloggers might have had a download from before January 2007.

Lots of noise about noise.

Gavin,

It took me a while to solve the mystery of small differences between plots and tables, since both products are created from the same binary data set. Here is the solution:

My program produces the tables (txt files) with nint(100*data) and the plot files with "write F9.3" from the same data.

Makiko then rounds the plot file from 3 to 2 digits (F9.2) which is reasonable given the margin of error. Had I used F12.6, the number of differences would be almost zero, had I used F9.2 there would be no differences.

I used F9.3 because occasionally I was asked whether a small change was increased or decreased by roundoff - but I'll gladly change to F9.2 for future updates.

What I think would be more beneficial is to add (as we do in 1 isolated instance) an estimated margin of error to all our tables and plots, indicating how much we trust these numbers. It is a little complicated by the fact that they are a function of time, but giving one number for the early period and a second number for the last few decades should be sufficient.

I also think it would pay to take a look at the "graphs" section, drop or add some displays, and add to each display a small text indicating what we can (or cannot) learn from it, why one would be interested in it. Right now, it looks to me more like a random selection of graphs with a few maps thrown in for good measure.

It's probably not worth mentioning that some of the differences are due to the fact that the original map was created on January 12, 2007, when some December 2006 and earlier data may not have been reported yet.

Your display shows the effect of the correction only, hence may differ a little from 's. I'm bracing myself against accusations of white wash attempts.

In light of the recent fuss over the significance of the correction to the United States temperature record, I tracked down a copy of the data as it existed on August 1 st (from MSN's search engine cache) and made a direct comparison (something that was largely lacking in much of the coverage of this issue).

I am distributing the comparison numbers and a graphic made from them to many of the principle commentators on this issue. Feel free to use and redistribute this at will, though I would appreciate an acknowledgment if you do so.

Reto

Reto,

When I took over from Jay when he left (Jay displayed what Jim told him to, based on our 1999 temperature paper), the graph section had only five graphs.

Fig. A, global mean, annual mean using meteorological stations (Fig. 4 of the paper)

Fig. B, northern, low, southern latitude annual means (Fig. 5 of the paper)

Fig. C, global mean, monthly means (Fig. 8 of the paper)

Fig. D, U.S. mean, annual means (Fig. 6 of the paper)

Fig. E, global and low latitude means, seasonal means (Fig. 7 of the paper)

I added

Fig. A2 (land-ocean index) because Jim switched more to land-ocean than the station data, and now this is our standard, and I don't think we should remove this.

hemispheric means, I put it because somebody I forgot (outsider) requested, and I thought it may not be a bad idea, but if you don't like this, I can remove.

set of recent months maps because Jim is quite interested in these, but since I have my own temperature page, I can remove this, if you want to.

And then the top one with a linegraph and three maps. As I mentioned earlier, some people like this, including Jim. But if you hate this,

I can remove it also.

Makiko

CC: Makiko Sato <makis@giss.nasa.gov>, gavin@giss.nasa.gov, klo@giss.nasa.gov

Jim,

I did make those calculations (I assume you mean using only GHCN and hand-adjusting only St.Helena and Lihue, in both cases decreasing the trend, eliminating a 1C and .8C step, resp., as stated in our 1999 paper, also using our urban adjustment).

I only held them back because bringing in a new analysis at this time would confuse the situation beyond hope.

As far as the global means are concerned, the effect of our cleaning is slightly negative for the pre-1950 period, slightly positive thereafter, the biggest deviations are -.01C in 1922, +.01C in 2006; the change in the 1900-1999 (lin. trend) is .01C/century (i.e. without the cleaning it would decrease by .01C).

The US trend however is a different story though not surprising: In addition to the change caused by the USHCN modifications (+.30C for the 1900-1999 change, as noted in our 2001 paper: +.14 TOBS, +.16 station hist.adj), the other modifications added .08C/century to the trend. So the trend would decrease by .38C.

The deviations for the individual years caused by the cleaning range from -.13 in 1922 to +.37 in 2006. The optical impression this creates when you look at the table of data is totally misleading: the 1998 anomaly just happens to fall below 1C (.93C) whereas 1921,1931,1934 are above 1C (1.27,1.20,1.37C) !

Makiko,

As you pointed out to me, if I keep 4 decimal places rather than 3, rounding to 2 digits will no longer be different than rounding directly to 2 digits (and I still have the 3rd digit if needed). So I will use 4 digits for internal purposes in the future.

Jim,

There are 2 fine points, none of them of any importance, that might cause some extra problems:

- 1 - The USHCN file we got in 12/2000 only contained data up to and including 1999; hence the correction also affected year 2000.
- 2 - I adjusted the old data (1880-1999) to fit the newer data (2000-current) as we did with St.Helena and Lihue, rather than the other way round. I could easily change that, but that would again change all station data and I think it would be unwise to do so at this point.

Reto

On Tue, 2007-08-14 at 02:52 -0400, James Hansen wrote:

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station

moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected by adding the NOAA/NCDC adjustment near the end of the record to the 2001-2007 data, and it has been so corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data.

In an op-ed for the Washington Times (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the " U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century ♦ 2000, 2002, 2003, 2004

◆ plummeted even lower down the Hot 100. In fact,

every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even American: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings ◆ albeit without the fanfare that accompanied

the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website

http://www.nasa.gov/centers/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Jim,

The US plots and figures are not part of the standard analysis; once a year (in January) we create them in a separate step.

In the last posting visible to the public (done in Jan 2001) of the US annual temperature plot 1998 was indeed a little warmer than 1934. In order to notice that, you had to go to the plot and click on table data. As far as I know, nobody at GISS noticed that fact or gave it a second thought.

The next update was due in Jan 2008. Had we updated this figure every month, then due to late US station reports, at some point that ranking would have changed back to 1934 "beating" 1998. My guess is that it would have been in February for the following reason:

Ken downloads the GHCN data repeatedly until he sees some US stations included - they always seem to come in a day or 2 later than most other data. As you know, particularly in January there is pressure to do the update as soon as possible; so it is very likely that his final download in January did not include all US stations yet.

I of course wanted to see the impact of the correction only, hence I did the same analysis for the latest data with and without the correction. In both cases, as you reported, US-1934 was slightly warmer than US-1998.

Hope that clears it all up.

Reto

On Tue, 2007-08-14 at 13:27 -0400, James Hansen wrote:

Makiko, Reto, could you please clear this up. Other people keep saying the same thing that Demian does, i.e., that we previously claimed that 1998 was warmer than 1934. Is that right? I am quite sure that our 2001 paper shows 1934 slightly warmer, as we still find. Of course, scientifically this is all nonsense, as the difference of 0.02 is much less than the accuracy, so practically it should be stated as a tie. I know that whenever new stations are added to the record it can change things by small amounts. Did we once find 1998 as warmer??? Jim (I will be away from e-mail for a few hours).

On 8/14/07, DEMIAN MCLEAN, BLOOMBERG/ NEWSROOM:

Thanks, James. I'm not familiar with that paper from 2001. Is it not true, though, that NASA's rankings, as available at:

<http://data.giss.nasa.gov/qistemp/graphs/fig.D.txt>

now show 1934 as the hottest year, where 1998 used to hold that position?

thanks,
demian

Demian,

No, we have not changed ranking of warmest year in the U.S. As you will see in our 2001 paper we found 1934 slightly warmer, by an insignificant hair over, 1998. We still find that result. The flaw affected temperatures only after 2000, not 1998 and 1934.

Yes, our analysis algorithm is available, described fully in publication, and other researchers have taken that description, applied it to the raw data and come up with the same results that we get.

Don,

These are some desperate characters trying to make a mountain out of a mole hill. I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature

averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Don,

These are some desperate characters trying to make a
mountain out of a mole hill. I presume that my note

"A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our global temperature analysis each month. The flaw affected only 2000 and later, and only the United States.

The flaw, even when present (in 2000-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw. We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intend of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy. If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata available station by station for station moves, time-of-observation bias, etc. However, the only available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records. Because the effect was small, we did not notice it. This programming flaw is easily corrected, and it has been corrected.

Don et al.,

I saw this on the NASA news summary today.

Columnist Notes Changes In NASA's Temperature Data. In an op-ed for the Washington Times (8/13, 87K) Mark Steyn, a syndicated columnist who is also senior contributing editor for Hollinger Inc. Publications, senior North American columnist for Britain's Telegraph Group, North American editor for the Spectator, writes, "Something rather odd happened the other day. If you go to NASA's Web site and look at the " U.S. surface air temperature" rankings for the Lower 48 states, you might notice something has changed.

Then again, you might not. They're not issuing any press releases about it. But they have quietly revised their All-Time Hit Parade for U.S. temperatures.

The "hottest year on record" is no longer 1998, but 1934. Another alleged swelterer, the year 2001, has now dropped out of the Top 10 altogether, and most of the rest of the 21st century ♦ 2000, 2002, 2003, 2004 ♦

plummeted even lower down the Hot 100. In fact, every supposedly hot year from the '90s and Oughts has had its temperature rating reduced. Four of America's Top 10 hottest years turn out to be from the 1930s, that notorious decade when we all drove

around in huge SUVs with the air-conditioning on full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998 no longer America's record-breaker? Because a very diligent fellow called Steve McIntyre of climateaudit.com labored long and hard to prove there was a bug in NASA's handling of the raw data. He then notified the scientists responsible, and received an acknowledgment that the mistake was an "oversight" that would be corrected in the next "data refresh." The reply was almost as cool as the revised chart listings.

Who is this man who understands American climate data so much better than the National Aeronautics and Space Administration? Well, he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings ♦ albeit

without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and on....

Does anyone know what this guy is talking about? I checked the NASA website

<http://www.nasa.gov/centers/goddard/news/topstory>

[/2006/2006_warm.html](#), dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Subject: Media request (Brazil)

Dear Leslie Nolan,

I am a journalist from ÉPOCA, a weekly magazine in Brazil, and I would like to interview one spokesperson of Nasa about the changes in the data concerning average temperatures in the United States - which have changed the warmest year from 1998 to 1934.

I would like to talk to Mr. James Hansen but I have the idea of how he is busy and how my deadline is short (today, in fact). Then I would like to ask you for another researcher related to this issue. I have only one main question and it would be great to have Nasa's official position towards it:

- What is the meaning of the correction for global warming theory?

I hope you can help me with this simple request.
Thank you very much,

I look forward to hearing from you soon,

Best regards,

Leticia

To: lsorg@edglobo.com.br

Dear Leticia,

Some bloggers, misguided by their eagerness to report anything that could be used to debunk the "myth of global warming", mixed 2 unrelated stories (really: non-stories) together.

Story 1: Due to missing reports, instrumentation changes, recalibrations etc. temperature reports are imprecise, the estimated margin of error of annual US mean temperatures is about .1-.2C. We posted these temperatures in January and then again in July. During these 6 months, some late reports and corrected reports had been incorporated resulting in occasional changes of up to .02C (5-10 times smaller than the margin of error). Accidentally, these changes caused the #1 and #2 years which differ by .02C in both postings to change places.

The unexciting truth is that nobody ever knew or will ever know whether 1934 or 1998 was warmer in the US. Actually, 4 more years could really be number 1, given the margin of error. It's a race with 6 winners.

Story 2: A flaw was detected in the procedure that combined station data from 2 sources. This error only affected years 2000-2006; after correcting the flaw, US-temperatures decreased by .15C in these years - since this is just about equal to the margin of error, fortunately for me who made the error, the correction had no significant effect. The corrections affected the global means by .003C; since the margin of error for global means is .02C, we round to the nearest hundredth of a degree and the table of global means was unaffected.

I am sorry if that disappoints you.

Sincerely,

Dr. Reto A. Ruedy

PS. the flaw in story 2 is about equivalent to taking your temperature orally every day and then suddenly switching to a rectal thermometer and using the data without taking into account that the latter data are slightly higher. The correction I made was the equivalent to take both temperatures at the same time, then adjusting either all the oral or all the rectal temperatures accordingly to get a consistent series.

Hope that clears things up

I am working on an article about the data correction made by Nasa at U.S. temperature tables and I would like to clarify some few points about this issue.

- What is the meaning of this correction? It is being said that it could raise questions about the trustability of the studies released about global warming. What is Nasa's official position towards it?

We are a modeling group and the projections about global change are based on physics and chemistry, using models and observations of the changing composition of the atmosphere, not observations of the resulting temperatures; those can only be used after the fact as confirmation or contradiction of the theory.

The same people who think a .02C difference in US temperatures is sensational complain in most of their reports how unreliable these very measurements are. So in their view, the margin of error should be even greater than our estimated .1-.2C and I personally agree with them that it is probably closer to .3-.4C. Unfortunately, they don't realize that if this is true, then a .02C change is of absolutely no importance, just a sampling error.

- Does Nasa intend to go public to explain more about the data correction?

I explained in the leading background section on our main temperature web site what the error was at the same time as I exchanged the figures and tables. I even mentioned by name the lay person who alerted us to the possibility of a programming error. Since the corrections were within the margin of error, nothing further seemed to be required.

Later, Dr. Hansen wrote a more explicit statement and we put a link to that statement on our web site.

- Is the global warming theory in risk because of this correction?

No. Warnings about potential global warming have been voiced in Dr. Hansen's papers in the early 1980's when he was basically the only climatologist to do so, and the data that were gathered in the mean time only showed that he had, if anything, underestimated the consequences of our computations: we really can't afford to delay any action because of the misinformations of some people who know nothing except how to work the press.

- Do you believe that this correction could be used for political purposes?

Everything can be used and is used for political purposes in particular

if it concerns mathematical/scientific questions; because education in these fields is so poor in the US, that people who do know better can get away totally ridiculous statements (like a change in the temperatures 2000-2006 has anything to do with a change in 1934 !).

Dr. Reto, I am sending the questions to you via e-mail because I think it would be easier for you to answer (considering that my deadline is today) but I can call you if you prefer.

Dear Dr. Reto,

I have just read your e-mail and I think that it is really clear about the implications (or lack of them) of this correction.

But I would like to ask you just two specific points, that I think that are still interesting even with your explanation:

1) Do the Nasa intend to go public to clarify this case and provide media and society with an official statement?

Yes - what NASA would like to do is to use the media attention as an opportunity to educate the public about a truly serious situation. Exactly how they will do so - given the tiny size of the molehill that was blown up to enormous proportions - I don't know.

When in our January US table 1998 and 1934 changed places (in all our previous tables and publications US-1934 slightly beat US-1998) nobody noticed or cared about that change, much less made any kind of official statement. So why should we have to do it now ?

Small programming errors are made and corrected all the time; the one I made in 2000 was not the only one (like all other programmers, I make many mistakes every day - debugging usually finds them, but errors that have only small effects can survive for years).

2) Other question raised by this case is about the differences among American temperature stations and the used in other countries. It's being said that American stations are mostly at rural areas, which suffered less temperature variation than the cities. Is it correct?

One criticism that some people brought up was that weather stations near growing cities show rising temperature since the urbanization contributes a warming that would not be felt further away from the urban center.

This question was taken seriously, analyzed, it's effect compared to the margin of error and found to be of similar size to the margin of error. Nevertheless, we use an adjustment that makes the time series of urban stations behave exactly like the mean of the neighboring rural stations. If an urban station does not have neighboring rural stations, we do not use its data.

In spite of all this effort, the global warming deniers cling steadfastly to that effect.

Our analysis treats all stations the same way independent in which country they are located.

Reto

Thank you very much, once more,

To: Leticia Francisco Sorg - Redação Época - Editora Globo <lsorg@edglobo.com.br>

Dear Leticia,

I agree with your revised table; I don't know where your previous table comes from (I'll look into that).

To answer your question, given the existing sampling error (.1-.2C):

No - we cannot draw any conclusions about our planet from the US data (much less from the rankings you show below):

The US has been warming in the period 1980-2006 similarly to the period from 1920-1934; that earlier 15-year period then was followed by a cooling period and the same might be true for the current 25-year period. The annual US-mean changes are still large compared to any CO2 effect.

However, the global means show a totally different picture (global mean year-to-year changes being much smaller than US-mean year-to-year changes); and whereas no scientist, as far as I know, could make a convincing argument for an extended warming period in the US in 1920-1934, our 1982 model runs showed that the effect of CO2 should become noticeable in the global means within the next 2-4 decades. And sadly, the global (not the US) data now available showed that model was, if anything, underestimating the effect.

Sincerely,

Reto

On Wed, 2007-08-15 at 14:03 -0300, Leticia Francisco Sorg - Redação Época - Editora Globo wrote:

Dear Dr. Ruedy,

I would like to thank you very much for you attention and precise information.

The last point I would like to ask you is concerning the ranking of the warmest years in U.S.

I have organized the data from the previous and the correct table of temperatures and I got to this ranking:

Previous table

1°
1934
1°
1998
2°
1921
3°
1931
4°
2005
5°
1999

6°
2001
7°
1953
8°
1990
9°
1987

Revised table

1°
1934
2°
1998
3°
1921
4°
2006
5°
1931
6°
1999
7°
1953
8°
1990
9°
1938
10°
1939

As I've pointed in red, two years from 30's entered in the ranking of 10 warmest years in U.S.. Considering this change, would it be possible to say that the planet is becoming hotter and hotter?

Thank you once more,
Best regards,
Letícia

To: Leticia Francisco Sorg - Redação Época - Editora Globo <lsorg@edglobo.com.br>

Ok, I see, this is the table made one and a half years ago in January 2006, where the 2005 data still had a lot of reports missing.

We updated that in January 2007 and planned to do the next update in January 2008.

I recomputed the table with and without correcting the famous flaw; the table with the corrections is on the web. The other table was never on the web, so most people compare the new table to the Jan 2007 version.

Using the newest data and the old flawed program, the ranking would have been:

1934, 1998, 2006, 1921, 1931, 1999, 1953, 2001, 1990, 1938

i.e. only 2006 and 2001 dropped a little, the other affected years were not among the first 10.

The corresponding curves may be found on

http://www.columbia.edu/~jehl/distro_LightUpstairs_70810.pdf

To: Leticia Francisco Sorg - Redação Época - Editora Globo <lsorg@edglobo.com.br>

Dear Leticia,

This is even more speculative, some people still try to deny in spite of the data that it is warming at all. To observe that the warming accelerates would take even longer observation times, another 50-100 years.

It would be bad enough if it keeps increasing at the current rate of .2C/decade as it has since 1980. It briefly increased at almost that rate in the 1915-1945 period but then it stayed even or even decreased a little til about 1980. The period from 1880-1920 was a period of basically constant global temperatures.

Again, the frightening thing about today's temperature rise is that it was predicted 25 years ago based on solid physics. So chances are it will not stop until we deal with the cause of it ! The good thing is that we know the cause, and we could use that knowledge if people just paid attention to the experts rather than to the bloggers.

Reto

Assunto: Re: U.S. warmest years

Dear Leticia,

I agree with your revised table; I don't know where your previous table comes from (I'll look into that).

To answer your question, given the existing sampling error (.1-.2C):

No - we cannot draw any conclusions about our planet from the US data (much less from the rankings you show below):

The US has been warming in the period 1980-2006 similarly to the period from 1920-1934; that earlier 15-year period then was followed by a cooling period and the same might be true for the current 25-year period. The annual US-mean changes are still large compared to any CO2 effect.

However, the global means show a totally different picture (global mean year-to-year changes being much smaller than US-mean year-to-year changes); and whereas no scientist, as far as I know, could make a convincing argument for an extended warming period in the US in 1920-1934, our 1982 model runs showed that the effect of CO2 should become noticeable in the global means within the next 2-4 decades. And sadly, the global (not the US) data now available showed that model was, if anything, underestimating the effect.

Sincerely,

Reto

Dear Dr. Ruedy,

I would like to thank you very much for your attention and precise information.

The last point I would like to ask you is concerning the ranking of the warmest years in U.S.

I have organized the data from the previous and the correct table of temperatures and I got to this ranking:

Previous table

1°
1934
1°
1998
2°
1921
3°
1931
4°
2005
5°
1999
6°
2001
7°
1953
8°
1990
9°
1987

Revised table

1°
1934
2°
1998
3°
1921
4°
2006
5°
1931
6°
1999

7°
1953
8°
1990
9°
1938
10°
1939

As I've pointed in red, two years from 30's entered in the ranking of 10 warmest years in U.S.. Considering this change, would it be possible to say that the planet is becoming hotter and hotter?

Thank you once more,
Best regards,
Leticia

Here is my suggested revision:

Researchers at NASA's Goddard Institute for Space Studies in New York recently revised information on their global temperature record based on corrected data. The program that replaced for some US stations the 1880-1999 record by records that were adjusted for instrumentation and procedural changes, used the original source for the later years without modifying them to fit the adjusted data. The result was a discontinuity in year 2000 for the US stations involved. Since the necessary adjustment was positive for about half the stations and negative for the other half, the effect on US means was a discontinuity of +.15C, and of .003C for the global mean series. The researchers ...

Good catch; for internal purposes, more than half the data is enough in all cases; but for the web products, we definitely have to change that as long as any part of the missing data is in the future.

I'll change the programs correspondingly for the next update. This time, we'll have to do it manually.

Reto

One final quibble. In Fig A2, we now have the 5 year mean value for 2005 - which implies that 2007 data is being used in the calculation. But since 2007 isn't complete, that number will change by the end of the year. It might be cleaner not to calculate the that last value since it uses information that isn't seen (yet) in the annual average numbers.

Gavin

Quoting Reto Ruedy <rruedy@giss.nasa.gov>:

Makiko,

As you pointed out to me, if I keep 4 decimal places rather than 3, rounding to 2 digits will no longer be different than rounding directly to 2 digits (and I still have the 3rd digit if needed). So I will use 4 digits for internal purposes in the future.

It becomes clearer if we split that sentence into 2 sentences:

The flawed program replaced for some US stations the 1880-1999 record by records adjusted for instrumentation and procedural changes as it was supposed to. However, it used the original source for the years after 1999 without modifying them to fit the adjusted data.

Sorry for the long complicated sentence,
! Hope that makes it better.

Not sure about punctuation, but I added a "," before "as it was supposed to" - seems to improve legibility.

It becomes clearer if we split that sentence into 2 sentences:

The flawed program replaced for some US stations the 1880-1999 record by records adjusted for instrumentation and procedural changes, as it was supposed to. However, it used the original source for the years after 1999 without modifying them to fit the adjusted data. The result was ...

Sorry for the long complicated sentence,
! Hope that makes it better.

Here is my suggested revision:

Researchers at NASA's Goddard Institute for Space Studies in New York recently revised information on their global temperature record based on corrected data. The program that replaced for some US stations the 1880-1999 record by records that were adjusted for instrumentation and procedural changes, used the original source for the later years without modifying them to fit the adjusted data. The result was a discontinuity in year 2000 for the US stations involved. Since the necessary adjustment was positive for about half the stations and negative for the other half, the effect on US means was a discontinuity of +.15C, and of .003C for the global mean series. The researchers ...

This sounds much better but I think we should add:

"for the period 1880-1999"

at the end of the 1st sentence

and

"when the adjusted data ended"

at the end of the 2nd sentence or something like that.

Jim,

There are some more.

(1) The biggest error I made was that I didn't notice that you had exchanged Fig. 2 and 3.

Others are minor.

(2) Do you want to give the url http://www.columbia.edu/~jehl/distro_LightUpstairs_70810.pdf after "the e-mail sent last week" in the 3rd paragraph?

(3) Do you really mean "micrometer" not magnifying glass? I thought a micrometer measures thickness of a paper or something, but I am not sure.

(4) "relative hot" or "relatively hot"?

(5) ")" miising after "Dangerous" at the end of a paragraph.

Send me more before I may be able to read it

Makiko

Reto Ruedy <rruedy@giss.nasa.gov>

The Real Deal: Usufruct & the Gorilla

Fox, Washington Times, and their like have gone bananas over a flaw discovered in the computer program that produces global temperatures at GISS each month. They have even managed to get Congress and NASA Headquarters involved. Now we know what mom meant when she said "don't make a federal case out of it". Hey, what is really going on here?

The said computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001) http://pubs.giss.nasa.gov/docs/2001/2001_Hansen_etal.pdf The flaw affected temperatures only in the United States (by about 0.15°C) and only in 2000 and later. We corrected the flaw in the program, thanked the fellow who pointed it out, and thought that was the end of it.

[The correction: As explained in the e-mail sent last week, http://www.columbia.edu/~jeh1/distro_LightUpstairs_70810.pdf one improvement made in our 2001 analysis was to use USHCN (U.S. Historical Climatology Network) station records in the U.S. as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day of temperature measurements, etc. Our computer program presumed that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program instead picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream. Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

What we have here is a case of dogged contrarians who present results in ways intended to deceive the public into believing that the changes have greater significance than reality. They aim to make a mountain out of a mole hill. I believe that these people are not stupid, instead they

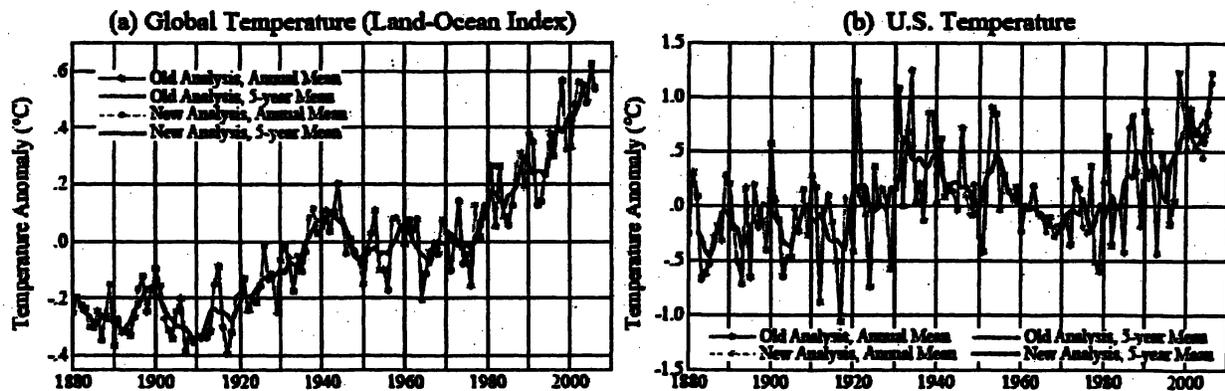

Figure 1. Global (a) and U.S. (b) before and after correction of flaw in computer program.

seek to create a brouhaha and muddy the waters in the climate change story. They seem to know exactly what they are doing and believe they can get away with it, because the public does not have the time, inclination, and training to discern what is a significant change with regard to the global warming issue.

The proclamations of the contrarians are a deceit, but their story raises a more important matter, usufruct. It is the most important issue in the entire global warming story, in my opinion. The players in the present U.S. temperature story, we scientists included, are just bit players. The characters in the main drama are big fish, really big fish. But before we get to that matter, I need to expose how the deceit works.

Instead of showing the impact of the flaw in our analysis program via a graph such as Figure 1, as a scientist would do (and as would immediately reveal how significant the flaw was), they instead discuss ranking of temperature in different years, including many false statements. We have thus been besieged by journalists saying "they say that correcting your error caused the warmest year to become 1934 rather than a recent year, is that right!?"

Hardly. First of all, many journalists had the impression that they were talking about global temperature. As you can see from Figure 1a, global warming is unaffected by the flaw. This realization should be enough to make most journalists lose interest, as global warming refers to global temperature.

But what if you are a chauvinist and only care about temperature in the United States? Did correcting the flaw in the program change the time of calculated maximum temperature to 1934? No. If you look at our 2001 paper, and get out your micrometer, you will see that we found 1934 to be the warmest year in the United States, by a hair, of the order of 0.01°C warmer than 1998, the same as the result that we find now. Of course the difference in the 1934 and 1998 temperatures is not significant, and we made clear in our paper that such years have to be declared as being practically a dead-heat.

Indeed, when we receive new data each month, which often adds in new stations, or modifies the results at a small number of stations, the results for a given year can fluctuate as much as a few hundredths of a degree. Also the GISS ranking of years is commonly different than that obtained from the NOAA or British analyses. This is expected, as there are significant differences in the methods. For example, the urban warming that we estimate (and remove) is larger than that used by the other groups (as discussed in 2001 Hansen et al. reference above).

Let's look (Figure 2) at the temperature anomalies in the four years that yield the warmest U.S. in our analysis. The U.S. mean temperature anomalies that we obtain range from 1.25°C in 1934 to 1.13°C in 2006. Thus the total range among these four years is just over a tenth of a degree. The uncertainty in the U.S. temperature is at least that large (see our published papers), so we can only say that these four years were comparably warm and the warmest year was probably either 1934 or 1998.

Note, however, that the 1998 and 2006 temperature anomaly maps differ fundamentally from the 1934 and 1921 temperature maps. In 1998 and 2006 the world as a whole has become warmer, 1998 being aided by a very strong El Nino, but 2006 by only a very weak El Nino. In 1921 and 1934 the United States happened to be a relatively hot spot compared to the world as a whole. The next time that the U.S. temperature happens to be unusually high relative to the globe, it may be quite a barn burner.

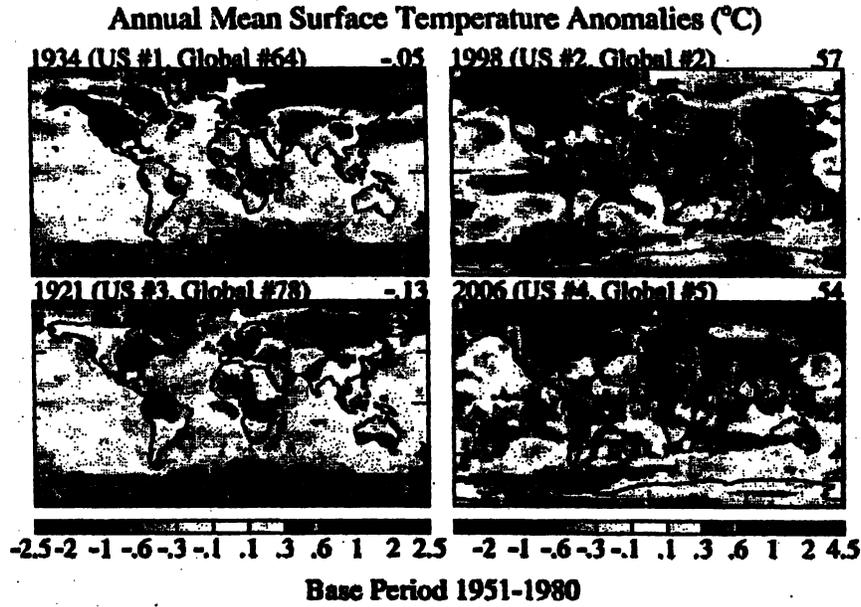

Figure 2. Temperature anomalies, relative to 1951-1980 base period, in the four years that are the warmest in the contiguous U.S. in the GISS analysis.

Although the media is always very interested in the ranking of individual years, the precise ranking is not only difficult to define accurately, it is also less important than the climate change averaged over several years. Figure 3 shows surface temperature anomalies of the past 10 years relative to both a 1880-1920 base period and the usual 1951-1980 base period. The figure also shows these results both with and without the flaw in our temperature analysis.

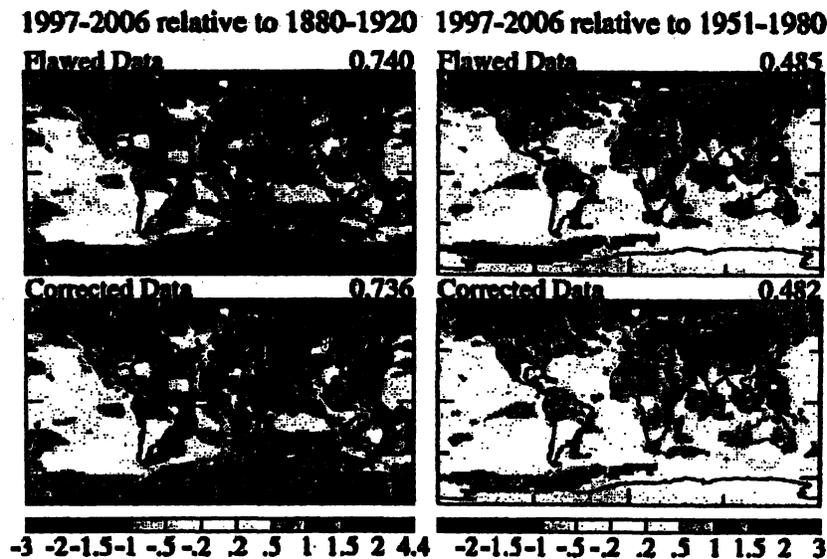

Figure 3. Surface temperature anomalies in the past 10 years (1997-2006) relative to two alternative base periods, 1880-1920 on the left and 1951-1980 on the right. The top row versus the bottom row shows the effect of the data flaw.

Over the past 30 years temperature isotherms have been moving poleward in the Northern Hemisphere land areas at a rate of about 50 km per decade. If the movements were fluctuations, their impacts would be limited. However, continual change of the same sense has a cumulative effect on the ability of species to survive in the presence of other stresses. Moreover, under business-as-usual growth of greenhouse gas emissions the rate of movement of isotherms could double this century, as discussed in several papers available on our web site, including "Dangerous" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_1.pdf "Trace Gases" http://pubs.giss.nasa.gov/docs/2007/2007_Hansen_etal_2.pdf

Implications of this rapid and growing global climate change are discussed in "The 800 Pound Gorilla: The Threat and Taming of Global Climate Change",

"Gorilla" <http://www.giss.nasa.gov/~jhansen/preprints/>

"Gorilla" is adapted from "The Threat to the Planet" (13 July 2006 New York Rev. Books) with assistance of Walter Simpson. "Gorilla" includes sidebars on 'Likely Consequences of Global Climate Change' and 'Three Policies Needed to Defuse the Global Warming Time Bomb'.

Usufruct. The deceit behind the attempts to discredit evidence of climate change reveals matters of importance. This deceit has a clear purpose: to confuse the public about the status of knowledge of global climate change, thus delaying effective action to mitigate climate change. The danger is that delay will cause tipping points to be passed, such that large climate impacts become inevitable, including the loss of all Arctic sea ice, destabilization of the West Antarctic ice sheet with disastrous sea level rise later this century, and extermination of a large fraction of animal and plant species (see "Dangerous", "Trace Gases", and "Gorilla" papers).

Make no doubt, however, if tipping points are passed, if we, in effect, destroy Creation, passing on to our children, grandchildren, and the unborn a situation out of their control, the contrarians who work to deny and confuse will not be the principal culprits. The contrarians will be remembered as court jesters. There is no point to joust with court jesters. They will always be present. They will continue to entertain even if the Titanic begins to take on water. Their role and consequence is only as a diversion from what is important.

The real deal is this: the 'royalty' controlling the court, the ones with the power, the ones with the ability to make a difference, with the ability to change our course, the ones who will live in infamy if we pass the tipping points, are the captains of industry, CEOs in fossil fuel companies such as EXXON/Mobil, automobile manufacturers, utilities, all of the leaders who have placed short-term profit above the fate of the planet and the well-being of our children. The court jesters are their jesters, occasionally paid for services, and more substantively supported by the captains' disinformation campaigns.

Court jesters serve as a distraction, a distraction from usufruct. Usufruct is the matter that the captains wish to deny, the matter that they do not want their children to know about. They realize that if there is no 'gorilla', then usufruct is not an important issue for them. So, with the help of jesters, they deny the existence of the gorilla. There is no danger of melting the Arctic, of destabilizing the West Antarctic ice sheet, of increasing hydrologic extremes, more droughts and stronger forest fires on one hand and heavier downpours and floods on the other, threats to the fresh water supplies of huge numbers of people in different parts of the globe. "Whew! It is lucky that, as our jesters show, these are just imaginary concerns. We captains of industry can continue with business-as-usual, we do not need to face the tough problem of how to maintain profits without destroying our legacy in our children's eyes."

Usufruct is as American as the Declaration of Independence, implicit in the Preamble "...to ourselves and our Posterity...". It is explicitly discussed in a famous letter of 6 September

1789 from Thomas Jefferson to James Madison, discussing the proposed Bill of Rights to be added to the Constitution: "The question whether one generation of men has a right to bind another. . . is a question of such consequences as not only to merit decision, but place also among the fundamental principles of every government. . . . I set out on this ground, which I suppose to be self-evident, 'that the Earth belongs in usufruct to the living' . . ."

Jefferson's philosophy regarding generational relations was based on this "self-evident" principle. That we have an obligation to preserve Creation for today's and future generations is a widely held belief. Native American Oren Lyons, a Faithkeeper in the Onondaga Nation, discusses the belief of Native Americans in their obligations to the "seventh generation". It is also a biblical paradigm that the Earth, Creation, is an intergenerational commons, the fruits and benefits of which should be accessible to every member of every generation.

Is the principle that the Earth belongs to us only in usufruct indeed self-evident and accepted by the public? In "Gorilla" I note the observation of Larry King that "nobody cares about 50 years from now". We can't take both positions. We need to make up our mind. Do we care?

I am puzzled by views expressed by some conservatives, views usually expressed in vehement unpleasant ways in e-mails that I have been bombarded by in the past several days. It is a bit disconcerting as I come from a moderately conservative state, and I consider myself a moderate conservative in most ways. It is puzzling, because it seems to me that conservatives should be the first ones standing up for preserving Creation, and for the rights of the young and the unborn. That is the basic intergenerational issue in global warming and the headlong use of fossil fuels: the present generation is, in effect, ripping off future generations.

Is it possible that conservatives have been too quick to support the captains of industry? If we allow industry to continue on a path of denial, to focus on their short-term profits, to deny the rights of our children, grandchildren and the unborn, if the planet passes climate tipping points, will we not share in the infamy, the infamy of the captains of industry?

It seems to me that the present situation, with only minimalist actions to mitigate global climate change, reflects, at least in part, the "success" of the disinformation campaign that the captains of industry have at least tolerated, and, in some cases, encouraged and supported. Of course Nature will, eventually, reveal the truth, but there is potentially great harm in the disinformation, because it increases the likelihood that we will pass climate tipping points.

The captains of industry are smarter than their jesters. They cannot pretend that they are unaware of climate change dangers and consequences for future generations. It is time for the captains of industry to rethink their positions. I do not mean, time to polish their image with marginal investments, 'green' advertisements, and other public relations gimmicks. I mean, time to consider how they will function as we move toward a cleaner world 'beyond petroleum', to invest in approaches that will help take us from here to there, and to begin to move smartly in that direction. There is still time to avert the most dramatic climate effects, if we promptly begin to address both CO₂ and non-CO₂ climate forcings. But just barely.

I am indebted to Jim Wine for schooling me in 'usufruct'.

Criticisms, as always, are welcome.

No - I'd like Jim to ok this version before it goes any further. I noticed that the various pieces did not fit together smoothly. But somebody should definitely check it.

So here is an attempt to put the pieces together; I also adjusted the beginning and end to fit the other modifications; please don't hesitate to further improve my style:

Researchers at NASA's Goddard Institute for Space Studies in New York recently revised information on their global temperature record after correcting a step in their data acquisition procedure. That process appropriately replaced some US station records with records adjusted for instrumental and procedural changes. However, it reverted to the unadjusted data after 1999, the last year for which the adjusted data were available. This resulted in a discontinuity in year 2000 for the US stations involved. The necessary adjustments turned out to be positive for about half the stations and negative for the other half, so the effect was reduced to a jump of +.15C for the US means, and a jump of +.003C for the global means, well within the margin of error. The researchers corrected the computer program and posted their revised data. More information is available here: (LINK TO GISS SITE).

To: lesgiss@verizon.net

Jim's email just came in - he changed one sentence (obviously he did not like my "jumps") - fine with me.

Below is the whole interaction as far as access questions are concerned.

Reto

----- Forwarded Message -----
From: Steve McIntyre <stephen.mcintyre@utoronto.ca>
To: rruedy@giss.nasa.gov
Subject: RE: Access to GISTEMP
Date: Thu, 17 May 2007 18:03:28 -0400

Thank you for this. I will observe this condition.

I realize that you have provided some documentation of what you did. In econometrics, it is a condition of publication in journals that authors archive their code and data so that their results can be routinely replicated. I realize that no such standards apply to climate science. However, equally, there is no prohibition on individual climate scientists voluntarily adopting these best practice standards. In that spirit, I would appreciate it if I could inspect the code used to process the GHCN data. Thanks, Steve McIntyre

To: Steve McIntyre
Cc: rschmunk@giss.nasa.gov
Subject: RE: Access to GISTEMP

After a short meeting with Dr. Hansen, we were advised to let you download whatever you want as long as generally accepted protocols are observed. Please try to do so at a time that does not impact other users, i.e. late nights, weekends.

What we did with the GHCN data is carefully documented in the publications listed on our website. We are not creating an alternate version of the GHCN data, we are mainly combining their data in various steps to create our anomaly maps.

Sincerely,

Reto A. Ruedy

On Thu, 2007-05-17 at 16:37 -0400, Steve McIntyre wrote:

In answer to your question, I'm interested in the data as it is presented to the public. All I was doing was downloading the data that is supposedly available to the public, but in a way that would not take 4 weeks of manual labor. If your version differs from the GHCN version, I'm interested in downloading your version so that I can assess the differences.

Cc: 'Robert B. Schmunk'
Subject: RE: Access to GISTEMP

Dear Steve,

Our main focus working with observed data is creating a gridded set of temperature anomalies which gives reasonable means over comparatively large regions - the global mean average being one of the major goals.

If

you are interested in individual stations, you are much better off working directly with the GHCN data.

Our station data are really intermediate steps to obtain a global anomaly map, and are not to be viewed as an end result. A modified time

series for a particular location may be more representative for the surrounding region than for that particular location. So it is important

to use these data in the proper context.

All our publications and investigations deal with regional temperature anomalies and that is the only use these data are good for after our modifications.

If you still think that downloading our "scratch pads" is important to your investigations, please let me know exactly what stage after the raw

GHCN data you need and maybe an indication why you need it, and I'll try

to provide you with the necessary data.

Again, we are not trying to compete with GHCN as provider of station data; we are using their data for a very specific project and we made

perhaps unwisely - some of our tools that we used to test the various steps of our process available on the web.

Reto

On Thu, 2007-05-17 at 15:18 -0400, Steve McIntyre wrote:

I know how to use the GHCN data. I'm not interested in "tips" on how to use it.

I'm interested in the versions as used by GISS. The GHCN version is convenient to download and I see no reason why GISS versions should not

be available on equivalent terms.

To: Steve McIntyre
Subject: Re: Access to GISTEMP

Please contact the GISTEMP group and inquire if they are willing to provide you with the dataset(s) from which the website applications extract information.

If they are not (I do not know what their current policy on this), then you can go a step closer to the source and obtain station data from the same location that the GISTEMP group obtains the original "raw" datasets that they work from. That is the Global Historical Climatology Network at <http://www.ncdc.noaa.gov/oa/climate/ghcn-monthly/index.php>

I'm not sure which specific files from the GHCN site are used. But if the complete GISTEMP data are not available then perhaps Dr. Ruedy of the GISTEMP group could give you some tips on how to use the GHCN data.

Good point. That was foolish of me to suggest checking a page on which access had been turned off.

I have turned off the restriction that I added to the server on data.giss.nasa.gov last night so that you can access the GISTEMP page and view the contact information.

I have been attempting to collate station data for scientific purposes.

I have not been running a robot but have been running a program

in

R

that collects station data.

It is an automated process scraping content from the website, and if that isn't what a web robot does, then it's close enough.

Subject: Re: Access to GISTEMP

Steve,

Although you did not provide any further details about your problem, I will assume that you are the person on the cable.rogers.com network who has been running a robot for the past several hours trying to scrape GISTEMP station data and who has made over 16000 (!) requests to the data.giss.nasa.gov website.

Please note that the robots.txt file on that website includes a list of directories which any legitimate web robot is forbidden from trying to index. That list of off-limits directories includes the /work/ and /cgi-bin/ directories.

Because the robot running on the cable.rogers.com network has rather obviously and blatantly violated those rules, I placed a block on our server restricting its access to the server.

If you are indeed the person who has been running that particular web robot, and if you do need access to some large amount of the GISTEMP station data for a scientific purpose, then you should contact the GISTEMP research group to explain your needs. E-mail addresses for the GISTEMP research group are located at the bottom of the page at <http://data.giss.nasa.gov/gistemp/>

Hi Reto:

Please verify this final version is okay:

Researchers at NASA's Goddard Institute for Space Studies in New York recently revised their global temperature record after correcting a step in their data acquisition procedure. The prior process appropriately replaced some US station records with records adjusted for instrumental and procedural changes. However, it reverted to the unadjusted data after 1999, the last year for which the adjusted data were available. This resulted in a discontinuity in year 2000 for the US stations involved. The adjustments necessary to remove the discontinuity turned out to be positive for about half the stations and negative for the other half. The net effect of the prior flaw was to increase the mean US temperature by about 0.15C and global temperature by about 0.003C, changes that were within the margin of error. The researchers corrected the computer program and posted their revised data on 7 August 2007. More information is available here: (LINK TO GISS SITE).

Thanks.

Leslie,

It might be good to note, that Steve got the time line wrong; the first time he contacted us was AFTER and BECAUSE his massive downloads got blocked by our webmaster; he never contacted us before that event.

So the claim that he downloaded our data because we refused to honor any of his requests is pure invention.

Blocking that IP address was a routine action any webmaster would take if he sees that one particular user monopolizes access to his web site. He had no idea about the identity of the owner of the IP address.

After he contacted us, his name did not ring any bells; we assumed it was a researcher interested in all station data. Since our data are organized for users to view individual stations rather than for massive downloads, we thought we could help him by directing him to GHCN where we got the data from and where they are organized for easy download.

Some data providers insist that we don't pass on their data; we are asked to refer requests to them, since they want to keep control of the distribution of their data. That is why we have to clear any data requests with Dr. Hansen. We were able to do that the very same day.

His first request for "our code" came in the same email in which he thanked us for giving him full access to our data.

That request was so general, that we had no idea what code he was talking about. Only after consulting his blog site did we learn that he is under the false impression that we have secret software that can "fix" faulty data. Since we don't have any such software, we were unable to honor this particular request.

The truth is that all our programs are fully documented in the literature and on our web site. Their task is to combine the station data into a gridded data set of anomalies. No fixes are applied except a simple well-documented urban adjustment (that happens to reduce the warming trend more than other groups' adjustment schemes). No "magic fix" programs are used. Instead we estimate and take into consideration the resulting margin of error before we draw any conclusions, a habit that distinguishes serious researchers from pranksters.

On Thu, 2007-08-16 at 12:20 -0400, lesqiss@verizon.net wrote:

Hi Reto:

I have not heard from Jim about the McIntyre allegations of cutting off his IP address...but drafted this short response...what do you think???

On May 16, 2007, an IP address attached to a cable.rogers.com network made 16,000 attempts in several hours to scrape GISTEMP station data. The webmaster had noted that this large volume was dramatically slowing access to the site and data by other users. That address was blocked by the GISS

webmaster as it violated rules from using web robots to access off-limits directories. The webmaster had no idea of the identity of the user until Dr. McIntyre emailed the webmaster. He was then advised of the reason for his service denial and advised to contact the GISTEMP research group to explain data needs. On the 17th, Dr. McIntyre again inquired about his access and was again advised to contact the GISTEMP group. Dr. Reto Ruedy of the GISTEMP group contacted Dr. McIntyre to discuss his requests.

here we might add: ... requests in an effort to help him to get what he needed.

(need to add in details about his requests to provide data and/or in a format that we don't have-Reto??)

Shortly after that email exchange, Dr. McIntyre was advised that he could again begin downloading provided that he accepted generally accepted protocols, i.e. doing so at times so as to not adversely affect other users (late nights, weekends, etc.).

Date: Thu, 16 Aug 2007 15:19:09 -0400
To: "Winstein, Keith" <Keith.Winstein@wsj.com>

Hi Keith,

A systems person helped me get through ! Obviously, I like the tenor of your article and I seem to have been able to get most of the facts across.

There is one point that I was less than clear about: The main reason why the global mean is more useful than the US mean (independent of how many stations we use) is that the global mean shows much smaller annual variations being determined by the energy balance of the whole atmosphere and uninfluenced by how these imbalances happen to be distributed over the world. So whereas the US means fluctuate wildly from year to year with of .5-1.5C, the global means are much steadier (.1-.2C unless there is a massive volcano eruption) and any potential longterm trend is much easier to verify or disprove when looking at these data.

It was also useful to read what Steve told you - his and his people's (A.Watts) blogs sound very differently. He obviously noticed that their distortions of the truth went way beyond the acceptable limits. Unfortunately, transcripts of interviews he gave clearly show that he has no hesitation telling obvious lies, and under these circumstances any discussions seem pointless to me.

If anybody, including him, points out questionable data on our web site, we'll investigate and take the necessary steps to eliminate any potential flaws.

Reto

PS In the mean time your 2nd email arrived.

To: "POSAMENTIER, HENRY W" <HENRY.POSAMENTIER@chevron.com>

CC: Makiko Sato <makis@giss.nasa.gov>

Dear Dr. Posamentier,

As described in detail in the papers mentioned below, we did not try to think up any adjustments, but finessed the whole question as follows: We basically tweak the urban records so that they look exactly like their rural neighbors as far as the long term trend is concerned.

For each urban station, we compute a mean series based on all neighboring rural stations. If there are not enough rural stations near that urban station, we completely disregard the urban station. If the urban station is longer than the rural combination, the unsupported part of the urban station is dropped. Finally we find a best approximation to the difference between rural and urban series with a straight line or a line with a knee at a variable point and subtract that difference from the urban record.

For alternate approaches to this question, please contact USHCN. They employ a team of people working full time on observed data analysis. We are a modeling group and spend just enough time on observed temperature data to keep our temperature website up-to-date.

the issue is here that you are dealing with a hostile interviewer. In such circumstances, it is much better simply to point out clear errors. If you open up another front they will dive on that instead and abandon all the previous positions (since they are not sincere in any case).

It does however highlight the rhetorical power of saying that the code is secret and things are being kept from the public. It may still be worth putting up a clean version of the adjustment program on the website in order to have something to point to in such cases.

He never asked for the urban adjustment code; the first request was for "the code that processes the GHCN data". In the interview and on his blog site he asks for the code that "fixes" bad station data - we never claimed to have anything like that. Below he asks essentially for the gridding program. If we relent, his requests will become more insane so that he will always be able to claim that we hide something.

I still think our best defense is the fact that all our procedures are explicitly described and open to anyone who wants to code them in their favorite programming language. This is the proper way to audit our results (and that's what NOAA and other groups are doing).

I was ready to respond to the email below, but before I got around to it he came out with his prank and I have no intention to ever respond to him again.

Dear Dr Ruedy,

Thank you for this information and for the courteous acknowledgement at your website. I can now see where your post-2000 data comes from, but I remain unable to identify a digital source for your data prior to 2000 from available information. I have compared GISS raw to all the archived USHCN versions and have been unable to find a match for US data. In some cases, the differences are substantial.

Can you provide me with (1) a URL from which the U.S. data prior to 2000 (in the version that you used) can be downloaded. (2) If this is no longer possible due to the passage of time, could you please provide me with a copy of the data that you used (or upload it to an area of your FTP site) and also provide its provenance and date of acquisition? Obviously mere print citations are inadequate for this purpose.

I would like to assess the impact of these modifications on the US and global averages for myself. I would appreciate a copy of the source code used for these calculations.

Regards, Steve McIntyre

To: Steve McIntyre
Cc: James E. Hansen; gavin@giss.nasa.gov
Subject: Re: GISS Raw Data

Dear Sir,

As to the question about documentation, the basic "GISS Surface Temperature Analysis" page starts with a "Background" section whose first paragraph contains the sentence: "Input data for the analysis , . . . , is the unadjusted data of GHCN, except that the USHCN station records were replaced by a later corrected version". A similar statement appears in the "Abstract" and the "Introduction" section of our 2001 paper (JGR Vol 106, pg 23,947-23,948). The Introduction explains the above statement in more detail.

In 2000, USHCN provided us with a file with corrections not contained in the GHCN data. Unlike the GHCN data, that product is not kept current on a regular basis. Hence we used (as you noticed) the GHCN data to extend those data in our further updates (2000-present).

I agree with you that this simple procedure creates an artificial step if some new corrections were applied to the newest data, rather than bringing the older data in sync with the latest measurements - as I naively assumed. Comparing the 1999 data in both data sets showed that in about half the cases where the 1999 data were changed, the GHCN data were higher than the USHCN data and in the other half it was the other way round with the plus-corrections slightly outweighing the minus-corrections.

Although trying to eliminate those steps should have little impact on the US temperature trend (much less the global trend), it seems a good idea to do so and I'd like to thank you for bringing this oversight to our attention.

When we did our monthly update this morning, an offset based on the last 10 years of overlap in the two data sets was applied and our on-line documentation was changed correspondingly with an acknowledgment of your contribution. This change and its effect will be noted in our next paper on temperature analysis and in our end-of-year temperature summary.

The effect on global means and all our tables was less than 0.01 C. In the display most sensitive to that change - the US-graph of annual means - the anomalies decreased by about 0.15 C in the years 2000-2006.

Respectfully,

Reto A Ruedy

On Sat, 2007-08-04 at 17:28 -0400, Steve McIntyre wrote:

Dear Sirs,

In your calculation of the GISS "raw" version of USHCN series, it appears to me that, for series after January 2000, you use the USHCN raw version whereas in the immediately prior period you used USHCN time-of-observation or adjusted version. In some cases, this introduces a seemingly unjustified step in January 2000.

I am unaware of any mention of this change in procedure in any published methodological descriptions and am puzzled as to its rationale. Can you clarify this for me?

In addition, could you provide me with any documentation (additional to already published material) providing information on the calculation of GISS raw and adjusted series from USHCN versions,

including relevant source code. Thank you for your attention, Stephen
McIntyre

Jim,

Gavin suggested some time ago that we should do the analysis with the current USHCN.

I downloaded the "FILIN" USHCN data; the filled-in numbers are marked. So I can use or ignore them. I have to write a program anyway to reformat this file to the format used by GHCN. This includes the easy conversion from F to C, but they also use a different set of ID-numbers to characterize the station. So first, I'll have to construct and check a conversion table to identify the stations properly.

TOBS does not have the station history adjustment (SHAP) - FILIN has it and is the last stage before their urban adjustment. I can run with or without the filled-in data (filling in added .05C/century to the US mean trend in our analysis).

Once the new USHCN data are reformatted, it's just a question of what to do with years 2006 and 2007. Otherwise it's simply switching an input file.

I still think, Steve (in the Town Hall interview below and when he talks to anybody but us) mixes us up with Tom Karl's group - they "fix" station data, we don't. If we get this misunderstanding out in the open, it might die down as well.

I didn't suggest using their urban adjustment, but that the most up-to-date USHCN data may have more in the way of documented station adjustments and more data earlier on. The FILIN data do not include their urban adjustment as far as I can tell. I get the impression from the USHCN web site that you should be able to extract just the TOBS corrected data without the FILIN.

The point is to make sure that the difference between the earlier USHCN data set we were using and the latest version does not make a significant difference to the results. Since any independent replication of the GISS procedure will use the currently available data set (not the one we are using), we should probably be ahead of the game in understanding what impact it has.

As is usual in these cases, the smarter of the court jesters have already stopped talking about 1934 and are now pushing the transparency 'meme'. That has a lot more resonance....

Jim,

Gavin suggested some time ago that we should do the analysis with the current USHCN.

I downloaded the "FILIN" USHCN data; the filled-in numbers are marked.
So I can use or ignore them. I have to write a program anyway to

reformat this file to the format used by GHCN. This includes the easy conversion from F to C, but they also use a different set of ID-numbers to characterize the station. So first, I'll have to construct and check a conversion table to identify the stations properly.

Jim,

You could mention one other difference:

NCDC's curve is based exclusively on the 1221 closely examined and carefully corrected USHCN full data records, GISS's curve was culled from our GLOBAL analysis, i.e. from global maps produced by combining all available station records; this includes the part of the USHCN data that could be downloaded from USHCN's web site (ending currently with year 2005), but it also uses the remaining 541 US stations, and as far as the US mean is concerned, it is also impacted by the non-US stations located within 1200 km of the US border.

Reto

On Wed, 2007-08-29 at 03:41 -0400, James Hansen wrote:

Doyle,

We start from NCDC raw data, but the analysis method differs, as described in our 2001 paper. As you can discern from that paper, the factor that probably makes the difference regarding our relative rankings of 1934 and 1998 is the method of correcting for urban warming effects, ours yielding a somewhat larger correction. However, the end results are in very good agreement, as you can see by looking at the temperature curves.

Makiko, would you please make available your recent figure with global and U.S. temperature curves? Doyle, you will see that these years are practically indistinguishable. There is no way for anyone to be certain which year was warmer.

Doyle,

Since this is a technical question and Dr. Hansen is busy this afternoon, I'll answer it:

No, your statement is NOT correct; to get the US means, NCDC's procedure of only using the best stations is more accurate. If that were our goal, we would proceed in the same way. Actually, whenever we report on US means in our publications, we recompute all US means using only USHCN data.

My recommendation to you is to continue using NCDC's data for the US means and Phil Jones' data for the global means. Our method is geared to getting the global mean and large regional means correctly enough to assess our model results.

We are basically a modeling group and were forced into rudimentary analysis of global observed data in the 70's and early 80's since nobody else was doing that job at the time. Now we happily combine NCDC's and Hadley Center's data to get what we need to evaluate our model results. For that purpose, what we do is more than accurate enough. But we have no intention to compete with either of the other two organizations in what they do best.

Sincerely,

Reto

Jim

Thank you for sending this clarification. I also received the graphs from Makiko.

So is it correct to say that NASA's data is more accurate than NCDC's since it has more sources? In the media, it would be ideal to refer to one source rather than two. Traditionally we've used NCDC's data.

And globally, we usually use the Hadley Centre data...

Hi Marc,

Thanks for the information. I'll cc Jim, in case he wants to comment; but currently we have email overload.

Cheers,

Reto

On Thu, 2007-08-30 at 16:34 -0400, Marc Imhoff wrote:

Hi Reto,

Sorry for the late reply. I am slammed with the never ending Senior Review for Terra which seems to be more an instrument of torture than peer review these days.

I am assuming that the file you are referring to is the 1995 DMSP data set we ran through a thresholding process which reduced the lit area. It compared very well to the 1990 census estimates of urban places in the US. This was some time ago.

Go ahead and use your best judgement on listing it. It's a bit old which means that urban sprawl has no doubt expanded the footprint considerably. Areas we listed as 'peri-urban' have no doubt increased in urban density.

CIESSEN may something similar for more recent times . However, I don't know of any updates using the thresholding and validation methods we derived. We were never able to obtain funding from our program managers in Terrestrial Ecology to continue this work - they didn't see the value.

Any interest from your HQ sources? They should be wiser now.

Marc

Hi Marc,

I tried to send the note below to David Stutzer, but he must have left or changed his email address; maybe you can answer my questions or know how I may contact him.

In 2000, he sent us some US brightness data and we are still using it for our "urban adjustment" scheme (us-lights.txt).

Recently we had to deal with attacks from blogger McIntyre of hockey stick fame, and there is some pressure on us to make our whole temperature analysis available over the web - input files and source codes. I don't know whether we'll really go that far, but to be ready,

I'd like to ask you the following questions:

Were these data ever updated ?

Can the file "us-lights.txt" or a similar file be downloaded from the web ? In case the answer is no, would it be ok, if we made that file available from our web site ?

Sorry to have to bother you with this nonsense.

Cheers,

Reto

On 8/23/07, Jack Kaye <jack.a.kaye@nasa.gov> wrote:

Jim ♦ in attempting to close the loop on this so we can deal

with the legislative action, I wanted to see if we could come up with any more quantitative information. I looked at the longer text that you had the link to ("The Real Deal: Usufruct & the Gorilla).

First, it appears that the "XX July 2007" in your message below should be 7 August 2007.

In terms of 1934 vis a vis the more recent years, the key data I see from your text that may be worth citing are:

♦ The four warmest US years on record were 1921, 1934, 1998, and 2006

♦ The mean temperature anomaly in the US was 1.25 deg C in

1934 and 1.13 deg C in 2006, which is the ~ 1/10 degree difference between the two, which is smaller than the uncertainty in the actual numbers.

♦ In 1934 the US was warm relative to much of the rest of the world, while in 2006 the world was much warmer.

If these points are enough, we can try to get them into a short paragraph. How about this?

The computer program used by Dr. Hansen to create the temperature record is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen in a peer-reviewed publication from 2001. The flaw affected temperatures only in the United States and only after 2000. As explained by Dr. Hansen in an e-mail sent out on August 10, one of the improvements made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the United States as adjusted by Thomas Karl of NOAA's National Climatic Data Center and his colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day at which measurements were made, etc. Dr. Hansen's computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years. Unfortunately, adjusted USHCN data have not been available in near-real-time, and his computer program picked up the data for these same stations reported in the World Meteorological Organization's GHCN (Global Historical Climatology Network) data stream.

Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in the temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS computer program on 7 August 2007 with a note to that effect made on the GISS Temperature web page. Based on the current analysis, the four warmest years in the US record were 1921, 1934, 1998, and 2006. The mean temperature anomaly in the US was approximately 1/10 degree C greater in 1934 (1.25 degrees) than in 2006 (1.13 degrees); this

difference is less than the uncertainty in the calculated mean. One point worth noting is that in 1934, the US was warm relative to much of the rest of the world, while in 2006, the warmth of the US was accompanied by that of much of the globe.

Would you be okay with this? If not, do you have suggestions? I don't know that we'd need much more than this!

On 8/15/07 6:18 AM, "Jack Kaye" <jack.a.kaye@nasa.gov> wrote:

Jim ♦ thanks for sending. I'll watch for next

installment. I appreciate the prompt turnaround (2:27 AM ♦ hope you're getting some rest). - Jack

On 8/15/07 2:27 AM, "James Hansen" <jhansen@giss.nasa.gov> wrote:

Jack, I am writing something, with figures, which I will send later today. Here are a few relevant paragraphs for now. Jim

The computer program is rerun every month as new meteorological station data and new satellite sea surface temperature data are reported. The program produces a global surface temperature field using an analysis scheme documented by Hansen et al. (2001).

The flaw affected temperatures only in the United States and only after 2000.

[As explained in the e-mail sent out last week, one of the improvements made in the 2001 analysis was to use the USHCN (U.S. Historical Climatology Network) station records in the United States as adjusted by Tom Karl and NOAA colleagues, who used available descriptive data to correct for effects of station moves, changes in time-of-day at which measurements were made, etc. Our computer program was written with the assumption that this (adjusted) USHCN data would also be used in future years.

Unfortunately, adjusted USHCN data have not been available in near-real-time, and our program picked up the data for these same stations reported in the WMO GHCN (Global Historical Climatology Network) data stream.

Because the GHCN data do not include the NOAA adjustments, this introduced a discontinuity in the temperature anomalies in 2000. This discontinuity can be removed by comparing USHCN and GHCN records just before 2000, and this correction was made to the GISS

computer program on XX July 2007 with a note to that effect made on the GISTEMP web page.]

How big an error did this flaw cause? That is shown by the before and after results in Figure 1. The effect on the global temperature record is invisible. The effect on U.S. average temperature is about 0.15°C beginning in 2000. Does this change have any affect whatever on the global warming issue? Certainly not, as discussed below.

:On 8/14/07, Jack Kaye <jack.a.kaye@nasa.gov> wrote:

Jim ♦ thanks for sending this to me.

We have an action to respond to a Congressional question about this. Can you provide us with a relatively straightforward answer (with some #) that we can transmit? I don't think we need anything extensive or complex, but a relatively brief (but quantitative) "just the facts" summary would help. As a backup, it may be good if we could have some # in case we get asked for more detail (e.g., list of top 20 warm years, time series of global T for last 15 years and also for 1934 ± 5 years).

Don is on travel, but may be checking e-mail.

Time scale is, of course, asap! -
Jack

On 8/14/07 2:52 AM, "James Hansen" <jhansen@giss.nasa.gov> wrote:

Don,

These are some desperate characters trying to make a mountain out of a mole hill.

I presume that my note "A Light on Upstairs?" should have clarified things for scientists (Leslie, you can send it to anybody), but perhaps a few of additional comments are warranted.

In summary: There was indeed a flaw* in our program that automatically updates our ~~global temperature analysis~~ each month. The flaw affected only 2001 and later, and only the United States.

The flaw, even when present (in 2001-2006, in the U.S.) was minor, at most a few thousandths of a degree on global mean and about 0.15C in the U.S. Contrary to some press reports, this did not change the rankings of global temperatures. Nor did it change our rankings of the top few years in the U.S., with 1934 the warmest in our record and 1998 practically tied with it. The claim in the news reports that suddenly 1934 has become the warmest U.S. year is nonsense. As you can see in our 2001 paper, 1934 was the warmest in our record then, and it is now, with and without the programming flaw.

We also point out in that paper that the differences among these different years are negligible, less than the uncertainty.

Finally, if one wished to be scientific, instead of trying to confuse the public, as is the obvious intent of these critics/contrarians, one should note that single year temperatures for an area as small as the U.S. (2% of the globe) are extremely noisy.

If one instead looks at the temperature averaged over several years, it is apparent that the U.S. as well as the world has been quite warm in the past decade. Indeed, averaged over several years, the U.S. is at its warmest point in the period of record, about 0.8C warmer than at the beginning of the 20th century, similar to the global mean warming.

Jim

*The flaw was caused by the fact that in our 2001 update of our analysis we included Tom Karl's adjustments to USHCN station records, which they based on metadata

~~available station by station~~
for station moves,
time-of-observation bias,
etc. However, the only

available data stream that included these stations after 2000 was the GHCN (WMO), which did not include the Karl adjustments, a fact not recognized by our program, thus causing a discontinuity in these station records.

Because the effect was small, we did not notice it. This programming flaw is easily corrected by adding the NOAA/NCDC adjustment near the end of the record to the 2001-2007 data, and it has been so corrected.

Don et al.,

I saw this on the NASA
news summary today.

Columnist
Notes Changes
In NASA's
Temperature
Data. In an
op-ed for the
Washington
Times (8/13,
87K) Mark
Steyn, a
syndicated
columnist who
is also senior
contributing
editor for
Hollinger Inc.
Publications,
senior North
American
columnist for
Britain's
Telegraph
Group, North
American
editor for the
Spectator,
writes, "
Something
rather odd
happened the
other day. If
you go to
NASA's Web
site and look
at the " U.S.
surface air
temperature"
rankings for
the Lower 48
states, you
might notice
something has
changed.

Then again,
you might not.
They're not
issuing any
press releases
about it. But
they have
quietly
revised their
All-Time Hit
Parade for

U.S.
temperatures.

The "hottest
year on
record" is no
longer 1998,
but 1934.
Another
alleged
swelterer, the
year 2001, has
now dropped
out of the Top
10 altogether,
and most of
the rest of
the 21st
century ♦

2000, 2002,
2003, 2004 ♦

plummeted even
lower down the
Hot 100. In
fact, every
supposedly hot
year from the
'90s and
Oughts has had
its
temperature
rating
reduced. Four
of America's
Top 10 hottest
years turn out
to be from the
1930s, that
notorious
decade when we
all drove
around in huge
SUVs with the
air-conditioning on

full-blast. If climate change is, as Al Gore says, the most important issue anyone's ever faced in the history of anything ever, then Franklin Roosevelt didn't have a word to say about it. And yet we survived.

So why is 1998
no longer
America's
record-breaker? Because a

very diligent fellow called Steve McIntyre of climateaudit.com
<<http://climateaudit.com/>> <<http://climateaudit.com/>> labored long and hard to
prove there was a bug in NASA's handling of the raw data. He then notified the
scientists responsible, and received an acknowledgment that the mistake was an
~~"oversight" that would be corrected in the next "data refresh."~~ The reply was
almost as cool as the revised chart listings.

Who is this

man who
understands
American
climate data
so much better
than the
National
Aeronautics
and Space
Administration? Well,

he's not even America: He's Canadian. Just another immigrant doing the jobs Americans won't do, even when they're federal public servants with unlimited budgets? No. Mr. McIntyre lives in Toronto. But the data smelled wrong to him, he found the error, and NASA has now corrected its findings ♦ albeit without the fanfare that accompanied the hottest-year-on-record hysteria of almost a decade ago. Sunlight may be the best disinfectant, but, when it comes to global warming, the experts prefer to stick the thermometer where the sun don't shine."

And he goes on and
on....

Does anyone know what
this guy is talking
about? I checked the
NASA website
<http://www.nasa.gov/centers>

/goddard/news/topstory/2006/2006_warm.html, dated Feb 8, 2007 and it shows the top five years as: 2005 (1st), 1998, 2002, 2003, and 2006.

Hi Jim,

This refers to a web site belonging to a person in England - at first sight, his analyses of GHCN data seem strangely naive, some inspired by McIntyre's blogs.

Anything we should do about this inquiry ?

Hello Dr Ruedy,

My name is Michael Cassin. I'm developing some technology for hosting online datasets and statistical analysis, and would like to inquire about the possibility of reproducing the GISS temperature data. I realise it is available through the web interface, but would like to know if there is an ftp, or other, site where the entire dataset can be downloaded. I'd also like to be sure of any copyright issues.

Apologies for the direct intrusion into your inbox. I would understand if you redirect my inquiry.

Best regards,

Mike Cassin

Jim,

I understand the need to make the programs and input files available. But to put out an unusable product (though it works on our machines, based on the directory structures, compilers, etc. of the various machines) that has to be repeatedly changed may be counterproductive. I wish I had another week - or at least a weekend where I could work without interruption.

(1) As far as list of stations we remove is concerned, most are removed or remain unused automatically because their records are too short to have sufficient overlap with the dominating stations. Do you only want a list of those stations that are explicitly removed at the beginning of the process due to their strange data ?

(2) Corrections: We correct 2 stations (St.Helena and Lihue) and use USHCN instead of the corresponding GHCN data. The rest is dropping parts or all of a record (=cleaning). Hence:

"no corrections"="not correcting the 2 stations, not using USHCN, no cleaning",

"current"="2 corrections+USHCN+cleaning",

"no cleaning"="2 corrections+USHCN".

Are any 2 of these 3 options what you need ?

I guess (3) can be done by Makiko, if not let me know.

On Thu, 2007-09-06 at 10:28 -0500, James Hansen wrote:

Reto, Robert,

We are getting more and more questions as to why we will not release our temperature data analysis programs. We need to make these available this week, by the end of the day tomorrow.

Can you put these in a place where they are accessible, with an address that I will put in an e-mail? This will be as part of an e-mail that also provides access to the revised "Peak Oil" paper.

It probably should include a simple listing of the function of each subroutine. We can note that a simplified version of the programs will be available in the future.

Finally we need:

(2) line graph of global mean land-ocean temperature index with and without these stations removed (the draft that you gave me has No Corrections, Current Web, No Cleaning -- what do these three

categories mean? I believe what we want is two curves, one that uses the data without alterations and one for what we present to the public (3) maps showing the results with and without our changes -- the four maps that you made for 1880-2006 are fine, but the maps need to be made with Makiko's program/color scale etc. Also I would like to add two maps: delete the two maps on the left (which show the effect of St Helena/Lihue) and add the result when South America and Africa are replace with no data, the objective being to see how these continents contribute to the global mean temperature change. Clearly the data in those continents is pretty lousy, but how much difference does that make for the global mean?

Jim

Jim,

I prepared a documentation file (preliminary version attached) that divides the process into a preliminary and another 5 steps - Jay's programs are in step 1 and Robert is working on it (he has trouble compiling one of the C programs; also the order in which stations are combined seems dependent on the release of the data base system); I'm currently working on step 2 and Ken is working backwards from step 6 - hope to get through by tomorrow and combine it into a semi-coherent package.

A week seems a reasonable estimate to clean up what was missed - a total rewrite of Jay's programs however might easily take longer.

Reto

On Thu, 2007-09-06 at 13:41 -0500, James Hansen wrote:

Yes, the perception is, unfortunately, what counts now. We will have to release them with the very strong recommendation that anyone wishing to actually use them should wait until they are cleaned up, with the estimate that this will take another week or so (is that the appropriate estimate to give?).

Yes, the list should be those stations explicitly removed, since that is perhaps the most subjective thing that we do to the data, other than the procedures for analysis that are described in the papers.

The "current" result is one of the results that we want to illustrate. For the other, I was thinking of excluding the correction of two stations and not dropping the stations that are on the list of removed stations (some of them might get removed by the analysis program, but that is o.k., it is using objective criteria). If you do not have this, but have something that includes it, for example also replacing USHCN of "current" with WMO, that should be all right.

The objective is too show that our partially subjective choice of stations to remove does not significantly alter the global warming that we obtain. A second objective is to show that the admittedly large problems with African and South American data does not significantly alter the inferred global warming (this second objective just requires Makiko to omit those areas).

GISS Temperature Analysis

History

GISS started in the 1970s to use 1-D models to study climate forcings and their potential impact. These studies were continued using the GISS 3-D climate model. However, comparisons with observed data were not easily possible, because long term temperature records (1880-present) are missing for large parts of the world and estimates for the global trends were not available in the literature. GISS started to compute such estimates on the basis of the available data using MCDW reports and NOAA near real-time data. GISS established that useful estimates can be obtained for the global temperature changes during the past century with a careful investigation of the margin of error of such estimates.

Fortunately, the labor-intensive effort of collecting reports from various sources and of evaluating and cleaning those reports was taken over by a team of experts at NOAA (GHCN/USHCN):

GISS now concentrates on converting these data to anomalies and combining them into a gridded data set to get time series of large regional and global means.

Sources

Basic data set: GHCN - <ftp://ftp.ncdc.noaa.gov/pub/data/ghcn/v2/v2.mean.Z> (data file)

v2.temperature.inv.Z (station information file)

For Hohenpeissenberg - http://members.lycos.nl/ErrenWijlens/co2/t_hohenpeissenberg_200306.txt

complete record for this rural station

(thanks to Hans Erren who reported it to GISS on July 16, 2003)

For US: USHCN - http://cdiac.ornl.gov/ftp/uschn_monthly/hcn_doe_mean_data.Z
station_inventory

For Antarctica: SCAR - <http://www.antarctica.ac.uk/met/READER/surface/stationpt.html>

<http://www.antarctica.ac.uk/met/READER/temperature.html>

<http://www.antarctica.ac.uk/met/READER/aws/awspt.html>

SCAR contains some stations that are not part of GHCN - only those data are used that are marked by SCAR as final

USHCN are a subset of GHCN, but those data were adjusted for various recording and protocol errors and discontinuities; this set is particularly relevant if studies of US temperatures are made. These corrections, obviously, contribute little to the GLOBAL temperature trend (since the data for the remaining 98% of the world are not as carefully investigated)

Step 0 : Merging of sources (do_comb_step0.sh)

GHCN contains reports from several sources, so there often are multiple records for the same location. Occasionally, a single record was divided up by NOAA into several pieces, e.g. if suspicious discontinuities were discovered.

USHCN and SCAR contain single source reports but in different formats/units and with different or no identification numbers. For USHCN, the table "ushcn.tbl" gives a translation key, for SCAR we extended the WMO number if it existed or created a new ID if it did not (2 cases). SCAR stations are treated as new sources.

Adding SCAR data to GHCN:

The tables were reformatted and the data rescaled to fit the GHCN format; the new stations were added to the inventory file. The site temperature.html has not been updated for over a year; we found and corrected a few typos in that file.

Replacing USHCN-unmodified by USHCN-corrected data:

The reports were converted from F to C and reformatted; data marked as being filled in using interpolation were removed. USHCN-IDs were replaced by the corresponding GHCN-ID. The latest common 15 years for each station were used to compare corrected and uncorrected data. The offset obtained in that way was subtracted from the corrected USHCN reports to match any new incoming GHCN reports for that station (GHCN reports are updated monthly, in the past, USHCN data lagged by 2-5 years).

Filling in missing data for Hohenpeissenberg:

This is a version of a GHCN report with missing data filled in, so it is used to fill the gaps of the corresponding GHCN series.

Result: v2.meanz

~~Step 1 : Simplifications, elimination of dubious records, 2 adjustments~~
~~(do_comb_step1.sh)~~

The various sources at a single location are combined into one record, if possible, using a method similar to the reference station method. The shift

is determined in this case on series of estimated annual means.

Non-overlapping records are viewed as a single record, unless this would result introducing a discontinuity; in the documented case of St.Helena the discontinuity is eliminated by adding 1C to the early part.

Some unphysical looking segments were eliminated after manual inspection of unusual looking annual mean graphs and comparing them to the corresponding graphs of all neighboring stations. (As a test, the analysis was done including all these parts - the global mean series was not affected)

After noticing an unusual warming trend in Hawaii, closer investigation showed its origin to be in the Lihue record; it had a discontinuity around 1950 not present in any neighboring station. Based on those data, we added 0.8C to the part before the discontinuity.

Step 2 : Splitting into zonal sections and homogeneization (do_comb_step2.sh)

Since the gridding program was written about 30 years ago for what now would be viewed as tiny machines, the data were divided into 6 zonal sections. We plan to reprogram the gridding and analysis section of our procedure to eliminate this division.

The goal of the homogeneization effort is to avoid any impact (warming or cooling) of the changing environment that some stations experienced by changing the global trend of any non-rural station to match the global trend of their rural neighbors. If no such neighbors exist, the station is completely dropped, if the rural records are shorter, part of the non-rural record is dropped.

Step 3 : Gridding and computation of zonal means (do_comb_step3.sh)

A grid of 8000 grid boxes of equal area is used. Time series are changed to series of anomalies. For each grid box, the stations within that grid box and also any station within 1200km of the center of that box are combined using the reference station method.

A similar method is also used to find a series of anomalies for 80 regions consisting of 100 boxes from the series for those boxes, and again to find the series for 6 latitudinal zones from those regional series, and finally to find the hemispheric and global series from the zonal series.

It should be noted that the base period for any of these anomalies is not necessarily the same for each grid box, region, zone. This is irrelevant when computing maps of trends; however, when used to compute anomalies, we always have to subtract the base period series from the series of the selected time period to get the proper anomaly map.

Step 4 : Regrid sea surface temperature anomalies

Sources: <http://www.hadobs.org> HadISST1: 1870-present
<ftp.emc.ncep.noaa.gov> cmb/sst/oimonth_v2 Reynolds 11/1981-present

For both sources, we compute the anomalies with respect to 1982-1991, use the Hadley data for the period 1880-11/1981 and Reynolds data for 12/1981-present. These data are replicated on the 8000-box equal-area grid in order to be able to use the same utilities for surface and ocean data. Areas covered by sea ice are masked out (a fixed mask is used for all times).

Step 5 : Computation of LOTI zonal means

The same method as in step3 is used, except that for a particular grid box the anomaly or trend is computed twice, first based on surface data, then

based on ocean data. Depending on the location of the grid box, one or the other is used with priority given to the surface data, if available.

The C programs mentioned are actually compiled C "extensions" which are used by the Python programs. I was able to install a copy of these extensions on Web2 in the spring two years ago when we managed to transfer the various GISTEMP CGI scripts from Web1 to Web2, but unfortunately I do not have any record of what special hoops I had to jump through in order to do so.

As for the database system, the Python programs save the station data in binary files using Berkeley DB. The version of BDB on the machine Jay and on the machine Web2 is different.

I have been able to get a Python script which combines station data records to run on Web2, but there are some differences in the resulting output files when compared with the files generated on Jay. I am currently trying to figure out what might be the cause of that, and whether it might be a result of the difference in BDB versions.

Reto Ruedy <rruedy@giss.nasa.gov>

Subject: US brightness index
From: Reto Ruedy <rruedy@giss.nasa.gov>
Date: Wed, 12 Sep 2007 16:07:08 -0400
To: jhansen@giss.nasa.gov, rschmunk@giss.nasa.gov
CC: makis@giss.nasa.gov, klo@giss.nasa.gov

Jim,

Steve is still having fun with step0, but eventually he'll find that we did not document how we determined the US brightness numbers we use in our homogeneization.

Checking that step, I noticed that the program that reads Stutzer's file is machine dependent, because some stations lie on the edge between 2 cells. If in these cases I use the brighter of the 2 cells the choices become more robust. 8 of the about 400 rural stations would become peri-urban, and since we don't distinguish between urban and peri-urban stations, these would be the only effective changes.

I looked at the US annual mean series in both cases: they differ by less than .003 C except between 1880 and 1900; in 1900 the difference new-old is -0.005C, in 1880 +.014C .

I would prefer to use add the newer version into the sources. I'd also like to take the text out of the tar file and make it available separately - this is probably the only thing that any normal person might be interested in. The big brightness file should probably also be stored separately for the convenience of those who would just want to look at the programs.

By the way, Steve's newest "discovery" about the Detroit file is simply due to our switch from USHCN-1999 to USHCN-2005.

He also claims (not in any email, just in his blogs - so it may not be true), USHCN-2006 is also available; I know that NOAA has it but I can't find it on the USHCN site.

Robert,

I combined all source codes according to the steps I outlined in my documentation and put it on jay:/gcm/GHCN/GISTEMP_sources . Please take a look at it - I tested most pieces. Maybe you find a better way to organize the thing.

The documentation "gistemp.txt" is not the final version. The whole thing is only about 5 MB.

I am currently trying to figure out what might be the cause of that, and whether it might be a result of the difference in BDB versions.

It turns out that the difference is in the version of Python installed on the computer. More specifically, it's the Python hashing function.

There are a couple places in comb_records.py where the records.items() command is used to get the separate records from the hash (or what Python calls a "dict") for a station that has multiple records. It is characteristic of a hash/dict that the items could be in any order, and it is up to the programmer to do his own sorting if it is required that the items be processed in a predictable order.

So because the hash function in Python 1.5 and 2.2 differs, when comb_records.py examines a station with multiple records and decides which records to use, the order in which those multiple records are assessed may vary and that can affect the output file.

I created a modified version of comb_records.py which always works through multiple records for a station in a predictable order (0, 1, 2, etc.). When that program was run on Jay and on Web2, the resulting output files were the same.

A similar hash ordering issue probably applies to the ~~comb_records.py program.~~

Makiko, Jim,

USHCN did a lot of cleaning since they gave us their data in 2000; in particular, much of the period 1880-1940 was changed or discarded for many stations - I mentioned that all the USHCN data we discarded were no longer there or were changed to look perfectly normal; also Steve's substantial Detroit Lakes changes were made sometime between 1999 and this year.

So it was much more than just adding the 6 extra years.

Jim,

Since answering Steve's question puts the blame for the changes on USHCN, and since he will probably demand again that we give him that old USHCN file, we should probably contact Tom Karl or Jay Lawrimore to find out how they want us to handle that situation.

I'll gladly write to them and would also ask about whether they actually made the 2006 USHCN data public as Steve keeps claiming.

Hi Jay,

Recently, we replaced - for our temperature analysis - the USHCN data you gave us back in 2000 (last stage before filling in missing data) by the file "hcn_doe_mean_data" (ending in 2005). Needless to say, this had little impact on our global analysis.

Recently, we have been approached by Steve McIntyre and his fans; in particular, he now is questioning some differences that originate in differences between the two USHCN files. He keeps insisting on seeing all our programs and input files, and I'm sure he bothered you - or whoever is in charge of USHCN now - with similar requests.

Four questions:

1 - Would it be ok with you if we made the old USHCN file publicly available ?

2 - Steve claims that USHCN data are publicly available to the end of 2006 - is that true and if so, where can I find it ?

3 - One person invoked FOIA to demand the release of the original temperature files that were used in 1999 as basis of one of our papers. Since you probably got similar requests, how do you respond ? Do you really keep for ever any files that were used in any of your papers ?

4 - Is using "hcn_doe_mean_data" disregarding any filler for missing data (marked M) a legitimate use of that file, and is this equivalent to using the SHAP version ?

Jim, Makiko,

Since the changes mainly affect this page and the station data page, this is the proper place to put this section. We might want to add a link to it on the station data page.

On the station data page, we might also want to include the caveat, that only the raw GHCN data are suitable for local studies; the other stages are only useful to compute regional anomalies and trends for regions larger than 300,000 square miles.

It might be good to add in the "what's new" section to a) the corresponding graph as in c).

The section after "what's new" might profit from being titled "How does 2007 compare to the 2 hottest years?"

To: "Robert B. Schmunk" <Robert.B.Schmunk@nasa.gov>

CC: James Hansen <jhansen@giss.nasa.gov>, Makiko Sato <makis@giss.nasa.gov>

Robert,

There is also a typo in the September 2007 item in the sentence that starts: "Our quality control...."

... and all stations removed by it our available in a list.

should be replaced by

... and all station records removed by it are available in a list.
or better

... and a list of all station records removed by it is provided.

I also would replace "stations" by "station records" in the first (and also in the last) sentence of that item (since NOAA only removed parts - mostly the beginnings - of a station record, not the whole thing). Then, of course, the second sentence has to be adjusted also: "The records removed ... so we no longer remove any USHCN records."

In addition, it is not true that USHCN removed "all" the records that we used to remove, some of these records were changed, some stayed as they were. Sorry, that was my mistake. So here is my suggestion for that item:

September 2007: The ... through 2005). In this newer version, NOAA removed or corrected a number of station records before year 2000. Since these changes included most of the records that failed our quality control checks, we no longer remove any USHCN records. *) Our quality control is still applied to the non-USHCN stations and is described by Hansen et al.(2001). A list of all station records removed by it is provided. The effect ... *)

(No changes in the first and the last sentence)

*) On second thought, the September 2007 item starts out with the NOAA-1999 -> NOAA-2005 switch. Rather than describing the effect of that change, the rest of the item deals with our quality control, programs I would be hard pressed to even find, we have not used them in years. If I remember correctly, these programs flagged as suspicious many stations; then we looked at the annual or monthly plots of these stations and picked the data to be discarded.

So I would stop after "we no longer remove any USHCN records". By the way, the effect of that switch was a slight increase in the US trend (.04 C for the 1920-2006 change based on linear trends: .21C -> .25C for the 1920-2006 period), the global trends were not affected.

temperature are available here.

I think that you can put them up temporarily with the direct links to the Columbia web page, and later replace that to a link to just the graphs and discussion of the graphs extracted from the Columbia web page and placed in a GISS repository. That specific discussion of graphs should also note that discussion of the significance of the changes is included on the Columbia web site giving the location (and perhaps also the RealClimate location?) of the web site (it can just be the web site, without going directly to the articles on GISTEMP). I understand your concern, but to ignore the misinformation is also a concern.

On 9/16/07, Robert B. Schmunk <Robert.B.Schmunk@nasa.gov> wrote:

A preliminary re-working of the GISTEMP homepage is at

http://data.giss.nasa.gov/gistemp/index_new.html

Although very long, it could go up as-is in place of the current GISTEMP homepage except that the links to the Columbia webpage stuff are not there yet (i.e ., in the second para of the Aug 2007 update comments).

I am very concerned about linking directly to the PDFs on the Columbia webpage, whether here or on the graphs page as Makiko has already done, because it is transparent to the user that the PDFs are located on Jim's personal webpage. All they know is that they click on a link on a NASA webpage and they get a PDF. Hence the inattentive user (which would be most of them) would think the PDF is a NASA document.

So on Sunday I will try to make a pass through the PDFs and extract out the material which can be posted on a NASA webpage. I would assume this would mostly mean toning down or eliminating language re: skeptics and denialists.

Also, Makiko, I cleaned up the HTML of the "what's new" you put at the start of the graphs webpage. Is the "(a)", "(b)", "(c)" notation necessary? I left it there, but can't see that it needs to be there.

Jim,

We could fix this by changing "magnitude of the effect" by "relevance of the effect" which is obviously what you meant. Not that this will prevent him from further maligning us.

Reto

On Mon, 2007-09-17 at 09:05 -0400, Steve McIntyre wrote:

Dear Sirs,

I see that you have decided to report the change in methodology as requested in my previous email. While you should have reported the change in methodology when it was made, it is better late than never.

In your new webpage, you state: " This August 2007 change received international attention via discussions on various blogs and repetition by some other media, with no graphs provided to show the magnitude of the effect." This is incorrect and I request that you correct this statement. On Aug 6, 2007, at Climate Audit, <http://www.climateaudit.org/?p=1868> , the two graphs below were provided to estimate the magnitude of the effect. The first graph shown below estimated the impact on the U.S. temperature history at a little more than 0.15 deg C. Despite having no access to your source code, this proved to be an accurate estimate.

The next graph shown below shows the distribution of changes over the 1221 U.S. stations, which are very substantial in individual cases. Despite your professed concern for illustrating the impact of changes, you did not yourself provide any graph to show the magnitude of the changes on individual stations, nor did you even provide explicit notice on your webpage that any changes had been made.

Would you please correct the incorrect information on your webpage. This request is made pursuant to the Data Quality Act.
Yours truly,

Stephen McIntyre

Dear Sir,

As indicated in the description of our input files, we switched from the old year 2000 version of USHCN to the current version. The differences you noticed reflect corrections that were made by USHCN within the last six years.

Reto A. Ruedy

On Wed, 2007-09-12 at 15:38 -0400, Steve McIntyre wrote:

Dear Sirs, I notice that you've changed the historical data for some US stations since Sep 7, 2007. In particular, I noticed that temperatures for Detroit Lakes MN in the early part of the century were reduced by nearly 0.5 deg C. These changes are subsequent to your

changes in August 2007 for the changing versions. To my knowledge, there is no explanation for this most recent change and I was wondering what the reason is.

Figure 1. Difference between Sep 10, 2007 version of Detroit Lakes MN and Aug 25, 2007 version.

Thank you for your attention.

Regards,

Steve McIntyre

Dear Sir,

Thanks for bringing to our attention that the term "magnitude of effect" might be interpreted as "size" rather than "relevance", our obvious intent. We clarified our formulation correspondingly.

On Mon, 2007-09-17 at 09:05 -0400, Steve McIntyre wrote:

Dear Sirs,

I see that you have decided to report the change in methodology as requested in my previous email. While you should have reported the change in methodology when it was made, it is better late than never.

In your new webpage, you state: " This August 2007 change received international attention via discussions on various blogs and repetition by some other media, with no graphs provided to show the magnitude of the effect." This is incorrect and I request that you correct this statement. On Aug 6, 2007, at Climate Audit, <http://www.climateaudit.org/?p=1868> , the two graphs below were provided to estimate the magnitude of the effect. The first graph shown below estimated the impact on the U.S. temperature history at a little more than 0.15 deg C. Despite having no access to your source code, this proved to be an accurate estimate.

The next graph shown below shows the distribution of changes over the 1221 U.S. stations, which are very substantial in individual cases. Despite your professed concern for illustrating the impact of changes, you did not yourself provide any graph to show the magnitude of the changes on individual stations, nor did you even provide explicit notice on your webpage that any changes had been made.

Would you please correct the incorrect information on your webpage. This request is made pursuant to the Data Quality Act.
Yours truly,

Stephen McIntyre

Larry,

Steve now invokes the infamous "data quality act" to a comment Jim made on our temperature website, and cc'd his complaint to infoquality@nasa.gov (should probably be nasa.gov). Would you be able to find out what if anything we should do against this inane accusation.

His graphs do no such thing as show the "relevance of the effect"; he just shows the correction (without error bars) rather than the corrected and uncorrected curves as we do.

Dear Sirs,

Your revised webpage <http://data.giss.nasa.gov/gistemp/> contains the following incorrect statement: "This August 2007 change received international attention via discussions on various blogs and repetition by some other media, with no graphs provided to show the relevance of the effect."

This is incorrect and I request that you correct this statement. As I advised you previously, on Aug 6, 2007, at Climate Audit, <http://www.climateaudit.org/?p=1868>, the two graphs below showed the relevance of the effect to U.S. temperature history and to U.S. stations.

The first graph shown below showed that the error was relevant to U.S. temperature history - a topic specifically considered in Hansen et al 2001.

The NASA website provides individual station histories, as well as U.S. and global estimates. The graph below showed the error was relevant to individual U.S. station histories.

The claim that "no graphs provided to show the relevance of the effect" remains incorrect. Once again, please correct the false statement on the NASA webpage <http://data.giss.nasa.gov/gistemp/> . This request is made under the Data Quality Act.

Yours truly,

Steve McIntyre

Dear Sir,

Thanks for bringing to our attention that the term "magnitude of effect" might be interpreted as "size" rather than "relevance", our obvious intent. We clarified our formulation correspondingly.

Dear Mark,

In addition to abusing FOIA, these people now also start to invoke the Data Quality Act. Larry Travis suggested I contact you.

Can you advise us whether there is anything we have to do in response to the email below because of that act? In case you don't know, who should we ask? Is there a department at nasa with the email address infoquality@nasa.gov? (I assume there is no "nasa.giv")

As far as this case is concerned, the man either has no idea or pretends to have no idea that "relevance" and "non-zero size" are not identical. Rather than showing corrected and uncorrected graph (which are basically indistinguishable), he showed the difference of the 2 curves (which makes any estimate of the relevancy of the correction impossible). So we are sure that his claim is baseless.

Sincerely,

Reto

Dear Mr.

Ostrov Dikson (22220674000) seems to work fine again.

However, I can't believe that you ever could display Kronstadt (63826063001) since the only data GHCN has for that station are from 1844-1875 - and we only use data starting in 1880. Do you remember the name of the station that you displayed ?

Subject: Re: Fwd: Preliminary examination of HL87 bias method as applied to individual station records

Jim,

I dealt with him yesterday since some station graphs no longer appeared (probably as a consequence of some errors in the program used to automatically create the station data tables - a program he subsequently corrected). I had to clean out the work directory to make the utilities function again.

His inquiry and response definitely lacked McIntyre's haughty and aggressive tone. But we did not get into any discussions.

As far as his comments are concerned, I don't exactly remember how much freedom we gave Jay to design the procedure to combine station records at the same location and how much testing he did.

In the bias procedure used to combine anomaly series, we use a separate bias for each month, Jay uses a single annual bias to combine temperature series at the same location, but we require a shorter overlap period in that case (4 years vs 20 years - maybe that's why we made the switch from monthly to annual bias).

I don't remember why Jay ranked stations with respect to their sources and always starts with MCDW-data if such data are available rather than using length only - maybe for reasons of continuity (before using GHCN, MCDW was our main source).

I doubt very much that the specific way to handle multiple records matters as far as US or global mean series are concerned. That our method introduces no systematic bias is confirmed by the fact that our and NOAA's totally different approach gives virtually the same answers.

In our gridding program, we combine the records strictly according to length of records. Closeness might be an alternative, but a station near the center of a subgrid box with a 20-year record might create a short time series for that subbox based on a single station.

In Jay's case, closeness is moot, since all records refer to the same location.

Cc: cdmss@giss.nasa.gov
Subject: Re: Station ID 62103970000

Good morning!

In our procedure, the MCDW record of Claremorris (Ireland) survived (barely) step 1 as an individual series, since it was too short to be combined with the other sources.

It got dropped at the beginning of step 2 together with all records that did not contain at least 20 years of data.

For our purpose, this record had no use. More generally, records shorter than 4 years are not used by our procedure; if it helps to keep your program from crashing, you may as well disregard them right away.

By the way, I did carry out the analysis combining sources in the order of their length (rather than starting with MCDW). It caused a slight but insignificant increase in the temperature trend. The individual global annual means were affected by -0.003C (1910-1920) to +0.005C (1995-present), whereas the margin of error is of the order of magnitude of 0.1 C.

When Dr. Hansen comes back from travel, he will decide how much of this analysis will be put on the web.

As you see from your own mail, all GHCN data are rounded to the nearest tenth of a degree. So there is no point worrying about procedural modifications that affect station data anomalies by less than .1C. At the end of step 1 and step 2, we again round the data to the nearest tenth of a degree.

At the beginning of step 3, we subtract from each time series its 1951-1980 mean, hence any vertical shifts introduced by the "bias method" in step 1 will cancel out at that point.

Thanks for your interest,

Reto A. Ruedy

999.90
